box trailers that operate in California.³³⁰ The program is being phased in between 2010 and 2020. Small fleets have been allowed special compliance opportunities to phase in the retrofits of their existing trailer fleets through 2017. The regulation requires affected trailer fleet owners to either use SmartWay-verified aerodynamic technologies and SmartWay-verified tires or retread tires. The efficiency improvements are achieved through the use of aerodynamic equipment and low rolling resistance tires on both the tractor and trailer. EPA has granted a waiver for this California program.³³¹

(d) NHTSA Safety-Related Regulations for Trailers and Tires

NHTSA regulates new trailer safety through regulations. Table IV-1 lists the current regulations in place related to trailers. Trailer manufacturers continue to be required to meet current safety regulations for the trailers they produce. FMVSS Nos. 223 and 224³³² require installation of rear guard protection on trailers. The definition of rear extremity of the trailer in 223 limits installation of rear fairings to a specified zone behind the trailer.

NHTSA recognizes that regulatory and market factors that result in changes in trailer weight can potentially have safety ramifications, both positive and negative. NHTSA believes that the appropriate perspective is to evaluate the regulation and market factors in their entirety. One such factor is that incentives in the Phase 2 regulation could result in an average decrease in trailer weight. Since removing weight from trailers allows more cargo to be carried, fewer trips are needed to move the same amount of cargo, and fewer crashes—including fatal crashes—could occur. Fleets and other customers have a natural incentive to request lighter-weight trailers. From the trailer owners' perspective, reducing trailer weight not only allows them to increase cargo when they are near capacity, but also reduces fuel consumption whether the trailer is fully loaded or not. In pre-proposal meetings with trailer manufacturers, companies said that customers are requesting lighter-weight components when possible and manufacturers are installing them.

To further incentivize a shift to lighter weight materials, the Phase 2 program provides two compliance mechanisms, both of which are discussed later in this Preamble (Section IV.D.(1)(d) and Section IV.E.(5)(d), respectively). The first is a list of weight reductions from which manufacturers can select. The list identifies specific lighter-weight components, such as side posts, roof bows, and flooring. Manufacturers using these lighter-weight components achieve fuel consumption and GHG reductions that count toward their compliance calculations. The NPRM identified twelve components, ranging from lighter-weight landing gear (which receives credit for 50 pounds of weight reduction) to aluminum upper coupler assemblies (which receive credit for 430 pounds). See proposed section 1037.515 at 80 FR 40627. In addition, for a lighter-weight component or technology that is not on the list of specific components, the program provides for manufacturers to use the "off-cycle" process to recognize the weight reduction (Section IV.E.(5)(d)). Through these mechanisms, the program provides significant flexibility and incentives for trailer light-weighting.

NHTSA also recognizes that the aerodynamic devices that we expect may be adopted to meet the Phase 2 trailer standards inherently add weight to trailers. In comments on the NPRM, TTMA stated that they believe that this weight increase will result in added trips and increased numbers of fatal crashes. By its analysis, this additional weight—which TTMA estimates to be

250 pounds per trailer, will cause some trucks to exceed the trailer weight limits, necessitating additional truck trips to transport freight that could not be moved by the "weighed-out" trucks. By TTMA's analysis, these added trips would cause an additional 184 million truck miles per year and would result in 246 crashes and 7 extra fatal crashes, using an assumed crash rate of 134 collisions per 100 million VMT and a 3 percent fatality rate per crash. The agencies evaluated TTMA's estimate of additional fatalities and disagree with some of the assumptions made in the analysis. For example, the fatality rate used was developed in a study conducted for Idaho and is higher than the national average. According to FMCSA's 2014 annual report for "Large Truck and Bus Crash Facts" indicates there are less than 1.67 fatalities per 100 million vehicle miles traveled (VMT) by combination trucks in the U.S. for 2014. When multiplied by an estimated 184 million additional truck miles due to weighed-out trucks, the result is an increase of about 3 fatalities, or 2.7 fatal crashes.

Overall, the potential positive safety implications of weight reduction efforts could partially or fully offset safety concerns from added weight of aerodynamic devices. In fact, for this reason, we believe that the Phase 2 trailer program could produce a net safety benefit in the long run due to the potentially greater amount of cargo that could be carried on each truck as a result of trailer weight reduction.

(e) Additional DOT Regulations Related to Trailers

In addition to NHTSA's regulations, DOT's Federal Highway Administration (FHWA) regulates the weight and dimensions of motor vehicles on the National Network.³³³ FHWA's regulations limit states from setting truck size and weight limits beyond certain ranges for vehicles used on the National Network. Specifically, vehicle weight and truck tractor-semitrailer length and width are limited by FHWA.³³⁴ EPA and NHTSA do not anticipate any conflicts between FHWA's regulations and those established in this rulemaking.

Utility Trailer Manufacturing Co. (Utility) commented that reducing existing restrictions on trailer size and weight could help encourage the transition to new technologies and trailer designs. However, these size and weight restrictions are under the jurisdiction of FHWA, and are largely

controlled by the weight limits established by Congress in 1956 and 1974, the size limits established in the Surface Transportation Assistance Act of 1982, and the size and weight limits established in the Intermodal Surface Transportation Efficiency Act of 1991. Changes to these restrictions would require a broader process involving Congress and federal and state agencies, and is beyond the scope of the Phase 2 trailer program.

Wabash National Corporation (Wabash) stated that the agencies should seek to ensure that today's action harmonizes with safety regulations applicable to trailers. Specifically, Wabash highlighted NHTSA's work on rear impact guard standards and ongoing examination of side impact guards. Wabash stated new or revised requirements for impact guards could increase trailer weight. The agencies have analyzed the issues in the present rulemaking while fully considering NHTSA's safety regulations and rulemakings pertaining to trailers. The subject of a possible side guard requirement is in a research stage. As discussed in a July 2015 document, NHTSA is in the process of evaluating issues relating to side guards and will issue a decision on them at a later date.³³⁵ In December 2015, NHTSA issued a notice of proposed rulemaking proposing to adopt requirements of Transport Canada's standard for underride guards.³³⁶ NHTSA is currently assessing next steps on that proposal, and includes as part of its analysis consideration of impacts of any decisions on the fuel efficiency of the vehicles. With respect to Wabash's comment regarding the additional weight from aerodynamic devices, as discussed in the previous subsection, the agencies believe potential compliance paths incorporating lightweighting could offset the additional weight of aerodynamic devices in whole or in part.

B. Overview of the Phase 2 Trailer Program and Key Changes From the Proposal

The HD Phase 2 program represents the first time CO₂ emission and fuel consumption standards have been established for manufacturers of new trailers. As was proposed (80 FR 40257), the final standards will phase in gradually, beginning in MY 2018. New regulated trailers built on or after January 1, 2018 need to be certified to

³³³ 23 CFR 658.9.

³³⁴ 23 CFR part 658.

³³⁵ 80 FR 43663 (footnote 3) (July 23, 2015).

³³⁶ 80 FR 78417 (December 16, 2015).

the new CO₂ emissions standards.³³⁷ NHTSA fuel consumption standards are voluntary until MY 2021.

EPA and NHTSA proposed a trailer program, using appropriate aspects of the Phase 1 tractor program as a guide, including optional averaging provisions (*i.e.* optional averaging across a manufacturer's trailer fleet) as a flexibility for trailer manufacturers to meet the proposed standards. The comments from the trailer industry were nearly unanimous in opposing averaging. Commenters cited the highly competitive nature of the industry, combined with a wide range of product diversity among companies. Commenters believe that these two factors could result in a program that unfairly benefits the few larger companies with diverse offerings and would be impossible to implement for the many companies with limited product diversity. Additionally, compared to other industry sectors, trailer manufacturers noted that they often have little control over what kinds of trailer models their customers demand and thus limited ability to manage the mix and volume of different products. Specifically, Wabash and Utility stated that the dynamic and customer-driven nature of the industry, with many customer-specific requirements for each trailer order, makes it impossible for a manufacturer to predict what products they will produce in a given year. Utility stated that an averaging program will put manufacturers in the position of having to decide which customers receive trailers with aerodynamic devices and which receive trailers without devices. Utility added that averaging may force manufacturers to absorb the cost of aerodynamic devices, or it could cause customers to go to another manufacturer with sufficient credits to fill an order without using aerodynamic devices. Truck Trailer Manufacturers Association (TTMA) also submitted comments asking the agencies not to adopt averaging provisions. In contrast, Great Dane stated that averaging is an option manufacturers may need and recommended its inclusion in the final rule. The International Council on Clean Transportation (ICCT) said that they generally favor averaging since it gives manufacturers maximum flexibility in meeting standards while allowing for the technology deployment path that best matches a company's business strategy.

In order to balance the advantage of an averaging program in allowing for introduction of the most reasonably stringent standards for trailers with the concerns articulated by manufacturers, the final program accordingly limits the option for trailer manufacturers to apply averaging exclusively to MYs 2027 and later for full-aero box vans only. We believe this delay provides box van manufacturers sufficient time to develop, evaluate and market new technologies and to become familiar with the compliance process and possible benefits of averaging. This will also allow customers to become more familiar with the technologies and to recognize their benefits. See Section IV.E.(5)(b) for more details on the trailer averaging program. In the earlier years of the program, when the program does not provide for averaging, the program does provide each manufacturer with a limited "allowance" of trailers that do not need to meet the standards. See Section IV.E.(5)(a) below.

The agencies proposed standards for dry and refrigerated box vans that were performance-based, and that were predicated on a high adoption of aerodynamic technologies, lower rolling resistance (LRR) tires and automatic tire inflation systems (ATIS). We designed the compliance approach for these performance-based standards so that manufacturers would have a degree of choice among aerodynamic, tire, tire pressure, and weight-reduction technologies and could combine them as they wished to achieve the standards. See 80 FR 40257. This final program maintains this flexible approach, adding provisions that include options for using tire pressure monitoring systems (TPMS) and innovative weight-reduction technologies as part of manufacturer compliance strategies. Section IV.E.(2) below discusses the trailer compliance provisions.

We proposed "partial-aero" criteria for box vans with work-performing equipment that impeded use of aerodynamic technologies and we proposed that those "partial-aero" box vans would not have to adopt the most stringent standards in MY 2027; instead, they would maintain the MY 2024 standards. We also proposed design-based tire standards for non-box trailers that required adoption of LRR tires and ATIS. Finally, in recognition that some specialized box van designs are not very compatible with the aerodynamic technologies, the agencies established "non-aero" criteria for box vans. Box vans meeting the "non-aero" criteria will be subject to the same requirements as the non-box trailers. 80 FR 40259.

The proposed program was designed to include nearly all trailer types, with a limited number of exemptions or exclusions that we believed indicated off-road, heavy-haul or non-freight transporting operation. TTMA and the American Trucking Associations (ATA) provided comments suggesting that additional trailer types should be excluded from the program based on these trailers' typical operational characteristics. The agencies considered the suggestions of these commenters and of several individual trailer manufacturers, and we recognize that many trailers in the proposed non-box subcategory have unique physical characteristics for specialized operations that may make use of lower rolling resistance (LRR) tires and/or tire pressure systems difficult or infeasible. Instead of focusing on trailer characteristics that indicated off-highway or specialty use, the agencies have identified three specific types of non-box trailers that represent the majority of non-box trailers that are designed for and mostly used in on-road applications: Tank trailers, flatbed trailers, and container chassis. Because of their predominant on-road usage, the tire technologies adopted in this trailer program will be consistently effective for these non-box trailer types. Consequently, the final program as it applies to non-box trailers is limited to tanks, flatbeds, and container chassis. All other non-box trailers, about half of the non-box trailers produced, are excluded from the Phase 2 trailer program, with no regulatory requirements. See Section IV.C.(1) for the regulatory definitions of the trailers included in this program.

Wabash commented that partial-aero vans should be exempt in MY 2021 rather than MY 2027 as proposed, citing the need for multiple devices to meet the later standards. The agencies reconsidered the proposed partial-aero standards in light of this comment and recognize that it would likely be difficult for most manufacturers to meet the proposed MY 2024 standards without the use of multiple devices, and yet partial-aero trailers, by definition, are restricted from using multiple devices. For these reasons, the agencies redesigned the partial-aero standards such that trailers with qualifying work-performing equipment can meet standards that would be achievable with the use of a single aerodynamic device throughout the program, similar to the MY 2018 standards. The partial-aero standards do, however, increase in stringency slightly in MY 2021 to reflect

³³⁷ For an explanation of how EPA defines "model year" for purposes of the trailer program, see Section IV.E.(1)(a).

the broader use of improved lower rolling resistance tires.

The agencies also considered comments from manufacturers that were concerned about the cost and, availability of ATIS for the trailer industry. Wabash, Owner Operator Independent Drivers Association (OOIDA), the Rubber Manufacturers Association (RMA), American Trucking Associations (ATA), and Bendix asked that TPMS be allowed for trailer tire compliance in addition to ATIS. OOIDA said that operators prefer less expensive and easier to operate TPMS to ATIS. Wabash expressed concern that ATIS suppliers would not be able to meet demand should ATIS be required as a compliance mechanism for all trailers, especially in the early years of the program. Great Dane stated that their customers are not seeing consistent benefit of ATIS. ATA commented that trailer manufacturers should be allowed to use TPMS for compliance because they are increasingly effective, and some trailers used in heavy-haul applications would need an additional ATIS air compressor, which adds cost and weight that can be avoided by the use of TPMS. The California Air Resources Board supported the agencies' proposal to allow only ATIS for compliance since TPMS require action on the part of the driver to re-inflate affected tires and thus the benefit of the systems is dependent on driver behavior.

The agencies agree that TPMS generally promote proper tire inflation and that including these lower-cost systems as a compliance option will increase acceptance of the technologies. The final trailer program provides for manufacturers to install either TPMS or ATIS as a part of compliance. For full- and partial-aero trailers, the standards are performance standards, and the GEM-based compliance equation (described below) provides ATIS a slightly greater credit than it does for TPMS, to account for the greater uncertainty about TPM system effectiveness due to the inherent user-interaction required with systems that simply monitor tire pressure. These performance standards are based on the use of ATIS and the numerical values of these standards reflect the 0.2 percent increase in stringency. See Section IV.D.(1)(c) for additional information.

For non-aero box vans and non-box trailers, the standards are design standards, met directly by installation of specified technologies, not by using the compliance equation. As long as a manufacturer of these trailers installs either a TPMS or an ATIS (as well as lower rolling resistance tires meeting the specified threshold), the trailer will

comply, and either technology applies equally. We project that most design-based tire standards will be met with the less expensive TPMS, but trailers with ATIS will also comply. The effectiveness values adopted for ATI and TPMS in the trailer program are consistent with those in the tractor and vocational vehicle programs.

The agencies generated the proposed standards with use of EPA's Greenhouse gas Emissions Model (GEM) vehicle simulation tool, but for compliance we created a GEM-based equation that trailer manufacturers would use for compliance. See Section IV.E.(2)(a). We made several improvements to GEM based on public comment, and these improvements impacted the results of the model. We have re-created a compliance equation for trailers based on the updated model and are adopting the new equation as the means for trailer manufacturers to certify their trailers in Phase 2.

The agencies also proposed an aerodynamic device testing compliance path that would allow device manufacturers to submit performance test data directly to EPA for pre-approval. 80 FR 40280. We designed this alternative to reduce the test burden of trailer manufacturers by allowing them to install devices with pre-approved data and to eliminate the need to perform their own testing of the devices. Based on public comment, the agencies are adopting the aerodynamic device testing alternative in the final trailer program and are updating several of the provisions related to submission and verification of test data on those devices. See Section IV.E.(3)(b)(v).

The agencies considered five alternative programs in the proposal and extensively evaluated what were termed Alternative 3 and Alternative 4 in our feasibility analysis. 80 FR 40273. The final stringency of both alternatives was identical and each included three-year stages of increasing stringency. However, Alternative 4 represented an accelerated timeline that reached its final stringency in MY 2024. Alternative 3 included an additional three years to meet its final stringency in MY 2027. Alternative 5 was proposed in four stages, but would have a required much greater application rate of the most advanced aerodynamic devices, including aerodynamic technologies on non-box trailers. The agencies believed this alternative was infeasible for this newly-regulated industry and did not extensively evaluate it.

Public comment from the trailer industry unanimously opposed the accelerated timeline of the proposed Alternative 4. TTMA recommended that

the agencies adopt no mandatory requirements, and instead rely on a voluntary program for trailers. OOIDA supported standards less stringent than either Alternatives 3 or 4. Great Dane said that adoption of standards more stringent than Alternative 3 would considerably increase the probability of negative effects on stakeholders. Wabash questioned whether, under the accelerated timeline of Alternative 4, current technologies could be produced for all applications for which they would be needed, and with sufficient reliability. The International Food Service Delivery Association, the Truck Trade Association, and Schneider also opposed Alternative 4 for similar reasons. STEMCO, California Air Resources Board (CARB), ICCT, and American Council for an Energy-Efficient Economy (ACEEE) supported Alternative 4. The Environmental Defense Fund (EDF) supported Alternative 5, but with an accelerated schedule, saying technologies will be available to meet the Alternative 5 standards by 2024.

The final standards adopted for the Phase 2 trailer program have the same four-stage implementation schedule as the proposed Alternative 3, with standards phasing in for MYs 2018, 2021, 2024, and 2027 (NHTSA standards apply beginning in MY 2021). We received comments regarding adjustments to technology adoption rates in our baseline reference cases which the agencies found to be persuasive, and the resulting adjustments are described in Section IV.D.(2)(c). Additionally, the technology effectiveness values and projected adoption rates for each of the four stages of the program were updated in response to comments, to reflect new test data, and to account for a program without averaging.

C. Phase 2 Trailer Standards

These final rules establish, for the first time, a set of CO₂ emission and fuel consumption standards for manufacturers of new trailers that phase in over a period of nine years and continue to reduce CO₂ emissions and fuel consumption in the years to follow. These standards are expressed as overall CO₂ emissions and fuel consumption performance standards, considering the trailer as an integral part of the tractor-trailer vehicle.

The agencies believe that the trailer standards finalized here will implement our respective statutory obligations. That is, we believe that this set of standards represents the maximum feasible alternative within the meaning of section 32902(k) of EISA, and are

appropriate under EPA's CAA authority (sections 202(a)(1) and (2)).

These standards have the same implementation schedule as the proposed Alternative 3, with standards phasing in for MYs 2018, 2021, 2024, and 2027. In our consideration of the full range of comments, the agencies have adjusted elements of the proposed Alternative 3 in ways that address some of these comments, as discussed in Section 0 below. As discussed in Section IV.E.(5)(b), the option to apply averaging to meet these standards will be available starting with MY 2027, but will not be available in earlier model years.

The agencies did not propose and are not establishing standards for CO₂ emissions and fuel consumption from the transport refrigeration units (TRUs) used on refrigerated box trailers. Also, EPA is not establishing standards for hydrofluorocarbon (HFC) emissions from TRUs. See Section IV.C.(3) below.

(1) Trailer Designs Covered by the Trailer Program

As described previously, the trailer industry produces many different trailer designs for many different applications. The agencies are introducing standards for a majority of these trailers that phase in from MY 2018 through MY 2027; the NHTSA fuel consumption standards are voluntary until MY 2021. The regulatory definitions of the trailers covered by this program are summarized below and are found in 40 CFR 1037.801 and 49 CFR 571.3.

(a) Box Vans

Box vans are trailers with enclosed cargo space that is permanently attached to the chassis, with fixed sides, nose and roof. Trailers with sides or roofs consisting of curtains or other removable panels are not considered box vans in this program. Box vans with self-contained HVAC systems are considered "refrigerated vans." This definition includes systems that provide cooling, heating or both. Box vans without HVAC systems are considered "dry vans."

This rulemaking establishes separate standards for box vans based on length. Box vans of length greater than 50 feet are considered "long box vans."³³⁸ All vans 50 feet and shorter are considered "short box vans." The agencies requested comment on the proposed 50-foot demarcation between "long" and "short" box vans (80 FR 40258). CARB

and the Union of Concerned Scientists (UCS) commented on this issue, requesting that the demarcation be changed to 47 feet, such that 48-foot vans would be covered under the long box subcategory. CARB suggested that the performance of aerodynamic technologies such as skirts and boat tails on a 48-foot van would be more similar to the performance of the same technologies on a 53-foot van than on the 28-foot van used to evaluate short box performance. CARB also stated that 48-foot trailers are not pulled in tandem and thus have the potential to adopt rear devices for additional reductions.

The agencies agree that 48-foot vans are aerodynamically similar to longer vans and that 28-foot trailers are often used in tandem, reducing the opportunity for rear aerodynamic features. However, the agencies believe that the use of 48-foot vans is more similar to that of shorter trailers than to that of the long-haul vans that make up most the long box subcategory. Trailer manufacturers have indicated that 48-foot vans are mostly used in short-haul operations (e.g., local food service delivery) and consequently they travel less frequently at speeds at which aerodynamic technologies can be most beneficial. Also, 48-foot vans make up a relatively small fraction of long box vans.³³⁹ The agencies thus do not believe that standards predicated on the use of more effective aerodynamic technologies on 48-foot vans will provide a substantial enough additional reduction in CO₂ emissions and fuel consumption to justify more stringent standards for those trailers. For these reasons, the agencies are maintaining the proposed 50-foot demarcation between long and short box vans and are basing the standards for each van size category accordingly.

The trailer program identifies certain types of work-performing equipment manufacturers may install on box vans that may inhibit the use of aerodynamic technologies and thus impede the trailers' ability to meet standards predicated on adoption of aerodynamic technologies. For this program, we consider such trailer equipment to consist of a rear lift gate or rear hinged ramp and any of the following side features: A side lift gate, a side-mounted pull-out platform, steps for side-door access, a drop-deck design, or a belly box or boxes that occupy at least half the length of both sides of the trailer between the centerline of the landing

gear and the leading edge of the front wheels. See 40 CFR 1037.107(a)(1) and 49 CFR 571.3.

The agencies have also considered how "roll-up" or "overhead" rear trailer doors might inhibit the use of rear aerodynamic devices. TTMA, ATA, Great Dane, and Utility stated that roll-up doors are work-performing devices that can inhibit rear aerodynamic technologies. However, the agencies are aware of several existing aerodynamic devices designed to be installed near the rear of a trailer that can function regardless of the type of rear door. Also, in their comments, STEMCO indicated that additional rear aerodynamic technologies would be less likely to enter the market if the trailer program were to include roll-up doors on the list of work-performing devices above and the industry didn't demand an aerodynamic product to work with roll-up doors. The agencies recognize there may currently be limited availability of rear aerodynamic technologies for roll-up door trailers, yet we also understand that innovations and improvements continue for all trailer aerodynamic technologies. For this reason, the final trailer program includes an interim provision—through MY 2023—for box vans with roll-up doors to qualify for non-aero and partial-aero standards (as defined immediately below), by treating such doors as work-performing devices equivalent to rear lift gates. For MY 2024 and later, roll-up doors will not qualify as a work-performing device in this way; however, we expect that manufacturers of trailers with roll-up doors will comply using combinations of new rear aerodynamic technologies, in conjunction with improved trailer side and gap-reducing technologies as appropriate. See 40 CFR 1037.150.

As presented in Section IV.C.(2) below, the agencies are adopting separate standards for each of the same nine box van subcategories introduced in the proposal (80 FR 40256) and for the non-box category discussed below. Full-aero long box dry vans and full-aero long box refrigerated vans are those that are over 50 feet in length and that do not have any of the work-performing equipment discussed immediately above. Similarly, full-aero short box dry vans and full-aero short box refrigerated vans are 50 feet and shorter without any work-performing equipment. We expect these trailers to be capable of meeting the most stringent standards in the trailer program.

Long box dry vans and long box refrigerated vans that have work-performing equipment either on the underside or on the rear of the trailer that would limit a manufacturer's ability

³³⁸ Most long trailers are 53 feet in length; we are adopting a cut-point of 50 feet to avoid an unintended incentive for an OEM to slightly shorten a trailer design in order to avoid the new regulatory requirements.

³³⁹ Memorandum to Docket EPA-HQ-OAR-2014-0827: Evaluation of 50-Foot Trailer Length Demarcation to Distinguish between Long and Short Box Vans. July 18, 2016.

to install aerodynamic technologies may be designated as partial-aero vans for their given subcategory. The partial-aero standards are based on adoption of tire technologies and a single aerodynamic device throughout the program. Long box dry and refrigerated vans that have work-performing equipment on the underside *and* rear of the trailer may be designated non-aero box vans. Non-aero box vans are a single subcategory that have design-based tire standards.

For short vans, the standards are never predicated on the use of rear devices, since many 28-foot trailers are often pulled in tandem. However, we are not aware of any current legislative or regulatory initiatives that would allow tandem trailers longer than 33 feet in length, and therefore we believe that short vans of length 35 feet and longer are unlikely to be pulled in tandem in the timeframe of these rules. We are adopting separate criteria for partial- and non-aero designation for short vans based on a length threshold of 35 feet. If vans 35 feet or longer have work-performing equipment on the underside of the trailer, we expect manufacturers can install rear devices to meet the full-aero standards, but they have the option to designate these trailers as partial-aero dry or refrigerated short vans with reduced standards that can be met with tire technologies and a single aerodynamic device. If vans 35 feet and longer have work performing equipment on the underside and rear, manufacturers may designate them as non-aero box vans.

Short vans that are less than 35 feet in length are more likely to be pulled in tandem, making most rear aerodynamic devices infeasible. Since gap reducers alone are not sufficiently effective to replace a skirt and the shortest trailers are not expected to install rear devices, both dry and refrigerated vans that are shorter than 35 feet with work-performing equipment on the underside of the trailer may be designated non-aero box vans that can comply with tire technologies only. In addition, refrigerated vans that are shorter than 35 feet cannot install gap reducers because of the TRU. Consequently, all refrigerated vans shorter than 35 feet, irrespective of work-performing equipment, can be designated partial-aero short refrigerated vans whose standards can be met with skirts and tire technologies. See 40 CFR 1037.107(a)(1) and 49 CFR 571.3. Because the types of work-performing equipment identified here generally add significant cost and weight to a trailer, we believe that the reduced standards available for trailers using this equipment are unlikely to provide an incentive for manufacturers

to install them simply as a way to avoid the full aero standards.

(b) Non-Box Trailers

All trailers that do not meet the definition of box vans are considered non-box trailers in the trailer program. Several commenters requested a clearer distinction of the trailers that are included in the program. In response, the agencies are limiting the non-box trailer standards to three trailer types that have distinct physical characteristics and are most often driven on-highway: Tank trailers, flatbed trailers, and container chassis. Non-box trailers that do not meet the definitions below are excluded from the trailer program, as discussed in the following section.

Tank trailers are defined for the trailer program as enclosed trailers designed to transport liquids or gases. For example, DOT 406, DOT 407, and DOT 412 tanks would fit this definition. These non-box trailers can be pressurized or designed for atmospheric pressure. Tanks that are infrequently used in transport and primarily function as storage vessels for liquids or gases (*e.g.*, frac tanks) are not included in our definition of tank trailers and are excluded from the program.

Flatbed trailers for purposes of the trailer program are platform trailers with a single, continuous load-bearing surface that runs from the rear of the trailer to at least the trailer's kingpin. Flatbed trailers are designed to accommodate side-loading cargo, and this definition includes trailers that use bulkheads, one or more walls, curtains, straps or other devices to restrain or protect cargo while underway. Note that drop deck and lowboy platform trailers are not considered *continuous* load-bearing surfaces.

Finally, in the trailer program, container chassis are trailers designed to transport temporary containers. The standards apply to all lengths of container chassis, including expandable versions. The regulations do not apply to the containers being transported, unless they are permanently mounted on the chassis.

(c) Excluded Trailers

As in the proposal (80 FR 40259), the final trailer program completely excludes certain trailer types. However, in response to comments and an improved understanding of the industry, the agencies have changed our approach to excluding some trailer types.

In the proposal, we focused on excluding trailers based on characteristics that tended to indicate

predominant operation in off-highway applications. The American Trucking Associations (ATA) and the Truck Trailer Manufacturers Association (TTMA) provided comments suggesting that additional trailer types should be excluded from the program based on the trailers' typical operational characteristics, generally because of these trailers' limited on-highway operation. Also, Wabash requested that the program specify clearer criteria for excluding or exempting trailers.

The agencies considered all of the suggestions of the commenters, and we now believe that a different approach to excluding some trailer types is more appropriate. We recognize that many trailer types in the proposed non-box subcategory have many unique physical characteristics and are designed for specialized operations and it would be difficult to create a comprehensive list of traits that indicated off-road use. This wide array of trailer types would have made the proposed approach difficult to implement for both trailer manufacturers and for the agencies, since the usage patterns of many specialty trailer types can vary greatly. Some of these uses, especially off-highway applications, may make use of the proposed tire technologies for compliance difficult or infeasible and may limit their effectiveness. Additionally, the agencies are aware that many manufacturers that build these specialty non-box trailers are small businesses (fewer than 1000 employees), and they would incur a disproportionately large financial burden compared to larger manufacturers if they were subject to the standards.

For these reasons, instead of focusing our approach to excluding trailer types on trailer characteristics that indicated predominant off-highway use, the final program excludes all non-box trailer types except for three specific types that we believe are designed for and mostly used in on-road applications. These types are tanks, flatbeds, and container chassis, as defined in the previous subsection. We now consider this approach to be much clearer and more straightforward to implement than the proposed approach. Manufacturers of these types of trailers can easily obtain and install LRR tires and tire pressure systems, and achieve the most consistent benefit from use of these technologies. The trailer program excludes all trailers that do not meet the criteria outlined in Section IV.C.(1)(b) above, and specified in 40 CFR 1037.5 and in 49 CFR 535.3(e).

The final rule also excludes certain types of trailers based on design

characteristics, consistent with the proposed rule. More precisely, these excluded trailer types are sub-types of otherwise regulated trailer types, such as certain types of box vans. First, the rule excludes trailers intended to haul very heavy loads, as indicated by the number of axles. Specifically, the rules exclude all trailers with four or more axles, and trailers less than 35 feet long with three axles. For example, a 53-foot box van with four axles would be excluded. Also, we agree with Utility that spread-axle trailers may be more susceptible to tire scrubbing, and the program accordingly excludes trailers with an axle spread of at least 120 inches between adjacent axle centerlines. The axle spread exclusion does not apply to trailers with adjustable axles that have the ability to be spaced less than 120 inches apart. Finally, the rules exclude trailers intended for temporary or permanent residence, office space, or other work space, such as campers, mobile homes, and carnival trailers.³⁴⁰

Manufacturers of excluded trailers have no reporting or other regulatory requirements under the trailer program. See 40 CFR 1037.5 and 49 CFR 535.3 for complete definitions of the trailer types that the program excludes. However, where the criteria for exclusion identified above may be unclear for specific trailer models, manufacturers are encouraged to ask the agencies to make a determination before production begins.

(2) Fuel Consumption and CO₂ Standards

As described previously in Section I, it is the combination of the tractor and

the trailer that form the useful vehicle, and trailer designs substantially affect the CO₂ emissions and fuel consumption of the tractors pulling them. Note that although the agencies are adopting new CO₂ and fuel consumption standards for trailers separately from tractors, we set the numerical level of the trailer standards (see Section IV.D. below) based on operation with “standard” reference tractors in recognition of their interrelatedness. In other words, the regulatory standards refer to the simulated emissions and fuel consumption of a standard tractor pulling the trailer being certified.

Unlike the other sectors covered by this Phase 2 rulemaking, trailer manufacturers do not have experience certifying under the Phase 1 program (or under EPA’s criteria pollutant program). Moreover, a large fraction of the trailer industry is composed of small businesses and even the largest trailer manufacturers do not have the same resources available to them as do manufacturers in some of the other heavy-duty sectors. The standards and compliance regime for trailers have been developed with this in mind, and we are confident these standards can be achieved and demonstrated by manufacturers who lack prior experience implementing such standards.

The agencies designed this trailer program to ensure a gradual progression of both stringency and compliance requirements in order to limit the impact on this newly-regulated industry. The agencies are adopting progressively more stringent standards in three-year stages leading up to the

MY 2027,³⁴¹ and are including several options to reduce compliance burden in the early years as the industry gains experience with the program (see Section IV.E.). EPA will initiate its program in MY 2018 with standards for long box dry and refrigerated vans, which standards can be met with common tire technologies and SmartWay-verified aerodynamic devices and standards for the other regulated trailers based on tire technologies only. In this early stage, we expect that manufacturers of trailers in the other trailer subcategories will meet their standards by using tire technologies only. NHTSA’s regulations will be voluntary until MY 2021 as described in Section IV.C.(2).

Standards for the next stages, which begin in MY 2021, gradually increase in stringency for each subcategory, including the introduction of standards for short box vans that we expect will be met by applying both aerodynamic and tire technologies. The standards for partial-aero box vans are less stringent than those for full-aero box vans, reflecting that the standards for partial-aero vans are based on adoption of a single aerodynamic device throughout the program. This is in contrast to the proposed standards for partial-aero vans that were identical to the standards for full-aero vans through MY 2026.

Table IV–2 and Table IV–3 below present the CO₂ and fuel consumption standards, beginning in MY 2018 that the agencies are adopting for full- and partial-aero box vans, respectively. The standards are expressed in grams of CO₂ per ton-mile and gallons of fuel per 1,000 ton-miles to reflect the load-carrying capacity of the trailers.

TABLE IV–2—TRAILER CO₂ AND FUEL CONSUMPTION STANDARDS FOR FULL-AERO BOX VANS

Model year	Subcategory	Dry van		Refrigerated van	
	Length	Long	Short	Long	Short
2018–2020	EPA Standard	81.3	125.4	83.0	129.1
	(CO ₂ Grams per Ton-Mile)				
	Voluntary NHTSA Standard	7.98625	12.31827	8.15324	12.68173
2021–2023	(Gallons per 1,000 Ton-Mile)				
	EPA Standard	78.9	123.7	80.6	127.5
	(CO ₂ Grams per Ton-Mile)				
2024–2026	NHTSA Standard	7.75049	12.15128	7.91749	12.52456
	(Gallons per 1,000 Ton-Mile)				
	EPA Standard	77.2	120.9	78.9	124.7
2027+	(CO ₂ Grams per Ton-Mile)				
	NHTSA Standard	7.58350	11.87623	7.75049	12.24951
	(Gallons per 1,000 Ton-Mile)				
2027+	EPA Standard	75.7	119.4	77.4	123.2
	(CO ₂ Grams per Ton-Mile)				
	NHTSA Standard	7.43615	11.72888	7.60314	12.10216
	(Gallons per 1,000 Ton-Mile)				

³⁴⁰ Secondary manufacturers who purchase incomplete trailers and complete their construction

to serve as trailers are subject to the requirements of 40 CFR 1037.620 and 49 CFR 535.5(e).

³⁴¹ These stages are consistent with NHTSA’s stability requirements under EISA.

TABLE IV-3—TRAILER CO₂ AND FUEL CONSUMPTION STANDARDS FOR PARTIAL-AERO BOX VANS

Model year	Subcategory	Dry van		Refrigerated van	
	Length	Long	Short	Long	Short
2018–2020	EPA Standard	81.3	125.4	83.0	129.1
	(CO ₂ Grams per Ton-Mile)				
	Voluntary NHTSA Standard	7.98625	12.31827	8.15324	12.68173
2021+	(Gallons per 1,000 Ton-Mile)				
	EPA Standard	80.6	123.7	82.3	127.5
	(CO ₂ Grams per Ton-Mile)				
	NHTSA Standard	7.91749	12.15128	8.08448	12.52456
	(Gallons per 1,000 Ton-Mile)				

The agencies are not adopting CO₂ or fuel consumption standards predicated on aerodynamic improvements for non-box trailers or non-aero box vans at any stage of this program. Instead, we are adopting design standards that require manufacturers of these trailers to adopt specific tire technologies and thus to comply without aerodynamic devices. This approach significantly limits the compliance burden for these manufacturers, especially if they do not also manufacture box vans subject to the

aerodynamic requirements. The agencies are adopting these design standards in two stages. In MY 2018, the non-box trailer standards require manufacturers to use tires meeting a rolling resistance of 6.0 kg/ton or better and to install tire pressure systems. In MY 2021, non-box trailers will also need tire pressure systems and LRR tires at 5.1 kg/ton (the current SmartWay-verification threshold) or better. The standards require non-aero box vans, which we believe are largely at a

baseline rolling resistance 6.0 kg/ton today, to install tire pressure monitoring systems and tires at a rolling resistance of 5.1 kg/ton in MY 2018 and 4.7 kg/ton in MY 2021 and later (there are no further increases in standard stringency for these trailers after MY 2021). For non-box trailers and non-aero box vans, manufacturers may install either TPMS or ATIS for compliance.

Table IV-4 summarizes the two stages of these design standards.

TABLE IV-4—DESIGN-BASED TIRE STANDARDS FOR NON-BOX TRAILERS AND NON-AERO BOX VANS

Model year	Tire technology	Non-box trailers	Non-aero box vans
2018–2020	Tire Rolling Resistance Level (kg/ton)	6.0	5.1
	Tire Pressure System	TPMS or ATIS	TPMS or ATIS
2021+	Tire Rolling Resistance Level (kg/ton)	5.1	4.7
	Tire Pressure System	TPMS or ATIS	TPMS or ATIS

The agencies project that the standards for the entire class of regulated trailers, when fully implemented in MY 2027, will achieve fuel consumption and CO₂ emissions reductions of two to nine percent relative to mostly market-driven adoption absent a national regulatory program (see Section IV.D.(2)). Because of the rapid pace of technological improvement in recent years and the lead time of nearly a decade, the agencies expect that both trailer designs and bolt-on CO₂- and fuel consumption-reducing technologies will advance well beyond the performance of their present-day counterparts. Regardless, we expect that the MY 2027 standards for full-aero box vans could be met with high-performing aerodynamic and tire technologies largely available in the marketplace today. A description of technologies that the agencies considered in developing these rules is provided in Section IV.D., with additional details in RIA Chapter 2.10.

(3) Non-CO₂ GHG Emissions From Trailers

In addition to the impact of trailer design on the CO₂ emissions of tractor-trailer vehicles, EPA recognizes that refrigerated trailers can also be a source of emissions of HFCs. Specifically, HFC refrigerants that are used in transport refrigeration units (TRUs) have the potential to leak into the atmosphere.

In their comments, CARB said they believed that EPA underestimated the potential for TRU refrigerant leakage, and requested that EPA (1) initiate a TRU refrigerant “usage monitoring program” to support future evaluations of leakage; (2) create incentives for low- and zero-emission (e.g., cryogenic) TRUs; and (3) for EPA’s SNAP program to phase out the main TRU refrigerant (R404a) when viable alternatives are available. EPA did not propose any action related to TRUs in this rule, and CARB did not provide sufficient information for EPA to introduce new regulatory requirements for TRUs at this time. In general, however, EPA will continue to monitor the state of TRU technology and operation, and may

pursue appropriate action if warranted in the future.

We also note that EPA has separately proposed a regulation under Title VI of the CAA, specifically section 608. See 80 FR 69457 (November 9, 2015). This proposal would extend existing regulations on ozone depleting refrigerants to many alternative refrigerants, such as HFCs, which are the most common refrigerants used in TRUs.³⁴² If finalized as proposed, EPA would require that appliances like TRUs be subject to the applicable requirements of 40 CFR subpart F, including requirements for servicing by a certified technician using certified recovery equipment and for recordkeeping by technicians disposing of such appliances with a charge size between five and fifty pounds, which

³⁴² Under the proposal, the regulations would not be extended to equipment using a substitute refrigerant when that use of the refrigerant has been exempted from the venting prohibition, as listed in 40 CFR 82.154(a).

would include TRUs, to help ensure that the refrigerant is not vented.³⁴³

(4) Lead-Time Considerations

As mentioned earlier, although the agencies did not include standards for trailers in Phase 1, box van manufacturers have been gaining experience with CO₂- and fuel consumption-reducing technologies over the past several years, and the agencies expect that trend to continue, due in part to EPA's SmartWay program and California's Tractor-Trailer Greenhouse Gas Regulation. Most manufacturers of 53-foot box vans have some experience installing these aerodynamic and tire technologies for customers. Manufacturers of trailers other than 53-foot box vans do not have the benefit of programs such as SmartWay to provide a reliable evaluation and promotion of aerodynamic technologies for those trailers and therefore have less experience with those technologies. However, all trailer manufacturers have experience installing tires and the installation process does not change with the use of lower rolling resistance tires. Some manufacturers may not have direct experience with tire pressure systems, but we observe that they are mechanically fairly simple and can be incorporated into trailer production lines without significant process changes.

EPA is adopting CO₂ emission standards for long box vans for MY 2018 that represent stringency levels similar to the current performance level needed for SmartWay's verification and those required for the current California regulation. These standards can be met by adopting off-the-shelf aerodynamic and tire technologies available today. The agencies are adopting less stringent requirements for manufacturers of other highway trailer subcategories beginning in MY 2018 that can be met without use of aerodynamic technologies. Given that these technologies are readily available and are already familiar to the industry, the agencies believe, for both cases, that manufacturers have sufficient lead time to adopt these technologies and to implement the simplified compliance provisions introduced below and described fully in Section IV.E.

NHTSA's direction under EISA is to allow four model years of lead-time for new fuel consumption standards, regardless of the stringency level or availability of flexibilities. Therefore, NHTSA's fuel consumption

requirements are not mandatory until MY 2021. Prior to MY 2021, trailer manufacturers could voluntarily participate in NHTSA's program, noting that once they made such a choice, they will need to stay in the program for all succeeding model years.³⁴⁴

We believe there are technology pathways available today that manufacturers could use to comply with the standards when they are fully implemented in MY 2027. The agencies designed each three-year stage of the program as a gradual progression of stringency that provides sufficient lead-time for all affected trailer manufacturers to evaluate and adopt CO₂- and fuel consumption-reducing technologies or design trailers to meet these standards while meeting their customers' needs. The agencies believe that the burdens of installing and marketing these CO₂- and fuel consumption-reducing technologies at the stringency levels of this program are not limiting factors in determining necessary lead-time for manufacturers of these trailers. Instead, we expect that the first-time compliance and, in some cases, performance testing, will be more challenging obstacles for this newly regulated industry. For these reasons, the standards phase in over a period of nine years, with flexibilities to minimize the compliance and testing burdens especially in the early years of the program (see Section IV.E.). We are adopting provisions for manufacturers to use a GEM-based compliance equation in lieu of the GEM vehicle simulation tool, which will reduce the number of resources required to learn and implement the model. We are also finalizing compliance provisions that allow trailer manufacturers to use pre-approved aerodynamic test data from aerodynamic device manufacturers, which could eliminate a trailer manufacturer's test burden for compliance. As explained above, non-aero box vans and non-box trailers, which make up almost 20 percent of the regulated trailers, are subject to straightforward design-based tire standards throughout the program that require that they install qualified LRR tires and tire pressure systems with simplified compliance requirements. See Section IV.E. for a full description of the trailer compliance program.

The Rubber Manufacturers Association (RMA) expressed concern that the proposed program would not provide sufficient lead time for the development and production of LRR tire designs for some off-road applications.

As discussed above, the final program now excludes all trailer types that would generally be used in off-road applications, including all non-box trailers except tanks, flatbeds, and container chassis. Therefore, trailer types designed for off-road use do not have LRR tire requirements, and the final program should significantly reduce RMA's concerns about available lead time for special tire development. Additionally, we have adjusted the tire performance requirements for the LRR tires of the non-box trailer design standards.

D. Feasibility of the Trailer Standards

As discussed below, the agencies' determination is that the standards presented in Section IV.C.(2), are the maximum feasible and appropriate under the agencies' respective authorities, considering lead time, cost, and other factors. We summarize our analyses in this section, and describe them in more detail in RIA Chapter 2.10.

Our analysis of the feasibility of the CO₂ and fuel consumption standards is based on technology cost and effectiveness values collected from several sources. Our assessment of the trailer program is based on information from:

- Southwest Research Institute evaluation of heavy-duty vehicle fuel efficiency and costs for NHTSA,³⁴⁵
- 2010 National Academy of Sciences report of Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles,³⁴⁶
- TIAX's assessment of technologies to support the NAS panel report,³⁴⁷
- The analysis conducted by the Northeast States Center for a Clean Air Future, International Council on Clean Transportation, Southwest Research Institute and TIAX for reducing fuel consumption of heavy-

duty long haul combination tractors (the NESCCAF/ICCT study).³⁴⁸

- The technology cost analysis conducted by ICF for EPA,³⁴⁹ and
- Testing conducted by EPA.

As an initial step in our analysis, we identified the extent to which fuel consumption- and CO₂-reducing technologies are in use today. The technologies include those that reduce aerodynamic drag at the front, back, and underside of trailers, tires with lower rolling resistance, tire pressure technologies, and weight reduction through component substitution. For our feasibility analysis, we identified a set of technologies to represent the range of those likely to be used in the time frame of the rule. The agencies developed the CO₂ and fuel consumption standards for each stage of the program by combining the projected effectiveness of trailer technologies and the projected adoption rates for each trailer type. It should be noted that the agencies need not and did not attempt to predict the exact future pathway of the industry's response to the new performance standards for box vans. Rather, we demonstrated one example compliance pathway that could reasonably occur, taking into account cost of the standards (including costs of compliance testing and certification), and needed lead time. More details regarding our analysis can be found in Chapter 2.10 of the RIA.

(1) Technological Basis of the Standards

Trailer manufacturers can design a trailer to reduce fuel consumption and CO₂ emissions by addressing the trailer's aerodynamic drag, tire rolling resistance, and weight. Accordingly, the agencies investigated aerodynamic technologies (e.g., skirts and tails), low rolling resistance tires, tire pressure systems, and materials that could be used to reduce trailer weight. A description of these technologies, including their expected performance, can be found in Chapter 2.10.2 of the RIA. For box vans, the analysis below presents one possible set of technology designs by which trailer manufacturers could reasonably achieve the standards. However, in practice, trailer manufacturers could choose different technologies, versions of technologies, and combinations of technologies that meet the business needs of their

customers while complying with this program.

To minimize complexity, a single van is used to represent each box van trailer subcategory in compliance and in our feasibility analysis. Within the short box dry and refrigerated van subcategories (50-foot and shorter), the largest fraction of those trailers are 28 feet in length. Similarly, 53-foot vans make up the majority of the long box dry and refrigerated vans. Consequently, a 28-foot dry van is used to represent all lengths of short dry vans and a 53-foot dry van represents all lengths of long dry vans in this analysis and for compliance. Similar lengths represent the short and long refrigerated van subcategories. This means that manufacturers do not need to analyze the performance of devices for each trailer length in each subcategory. This approach provides a conservative estimate of CO₂ emissions and fuel consumption reductions for the longer vans within a given length subcategory,³⁵⁰ but the agencies believe that the need to avoid an overly complex compliance program, reinforced by most of the industry comments, justifies this approach.

(a) Aerodynamic Technologies

For box vans under these rules, aerodynamic performance of tractor-trailers is evaluated using a vehicle's aerodynamic drag area, C_dA. However, unlike the tractor program, the performance of trailer technologies is quantified using changes in C_dA (or "delta C_dA") rather than absolute values. This delta C_dA classification methodology, which measures improvement in performance relative to a baseline, is similar to the SmartWay technology verification program with which most long box van manufacturers are already familiar. The one difference is that, although EPA's SmartWay aerodynamic verification program uses a relative improvement, the metric is a percent fuel savings, whereas the compliance program for Phase 2 uses change in drag area, delta C_dA. Chapter 2.10.2.1.1 of the RIA provides a comparison of the SmartWay and Phase 2 metrics.

The agencies proposed to use a delta C_dA measured at zero-yaw (head-on wind) in the trailer aerodynamic test procedures (80 FR 40277). However, comments from several stakeholders

including ACEEE, CARB, ICCT, RMA, STEMCO, and Utility suggested that measurements that account for cross-wind provide a more appropriate measure of the benefits these technologies would experience in the real world, especially for technologies that are effective when the wind is at an angle. The agencies evaluated our own aerodynamic test data, including data collected to justify use of wind-average results in the proposed tractor program, and we recognize that the drag coefficient increases under cross-wind conditions likely seen in real-world operation. Since wind-averaging will account for this, and more appropriately capture aerodynamic benefits from many devices, including several small-scale devices, we are adopting a wind-averaged approach for aerodynamic testing in the trailer program. See Section IV.E.(3)(b)(ii) below and Chapter 2.10.2.1.2 of the RIA for a summary of yaw-angle effect as observed in our aerodynamic testing. The feasibility analysis that follows was performed using wind-averaged delta C_dA values.

(i) Aerodynamic Technologies for Non-Box Trailers

The agencies are aware that some side skirts have been adapted for the non-box trailers considered in this rule (e.g., tank trailers, flatbeds, and container chassis). CARB submitted comments noting that some of these technologies have shown potential for large reductions in drag. At this time, however, we are unable to sufficiently assess the degree of CO₂ and fuel consumption improvement that could generally be achieved across this segment of the industry and the associated costs of these technologies. In the case of each of the general non-box trailer types included in the trailer program, the range of physical trailer designs, including the areas where aerodynamic devices would be installed, is great, and technologies to date tend to be designed for narrow applications. This lack of basic information about the applicability of future technologies for these trailer types also inhibits our ability to estimate costs, either of the specific future designs themselves or of the size of the market for any particular product. As a result, we expect that standards predicated on aerodynamic technologies for these trailer types could result in relatively little emission and fuel consumption improvement at relatively high costs. We will continue to monitor this segment of the trailer industry in this regard and may consider further action in the future.

The agencies proposed to adopt design-based tire standards (*i.e.*

³⁴⁸ NESCCAF, ICCT, Southwest Research Institute, and TIAX. Reducing Heavy-Duty Long Haul Combination Truck Fuel Consumption and CO₂ Emissions. October 2009.

³⁴⁹ ICF International. "Investigation of Costs for Strategies to Reduce Greenhouse Gas Emissions for Heavy-Duty On-Road Vehicles." July 2010. Docket Number EPA-HQ-OAR-2010-0162-0283.

³⁵⁰ For example, aerodynamic devices on a 48 foot box van will perform somewhat better than on a 28 foot box van, so our analysis likely underestimates the benefits of these technologies. See Chapter 2.10.2.1.2.6 of the RIA and Memorandum to Docket EPA-HQ-OAR-2014-0827. "

standards not predicated on any aerodynamic technology, and for which neither GEM nor the GEM-based equation is required) for these trailers to eliminate the need for performance testing and to reduce the overall compliance burden for these manufacturers. 80 FR 40257. The data submitted and adoption rates suggested by CARB would not provide a large enough reduction in CO₂ and fuel consumption from non-box trailer aerodynamics to justify the increased burden on these manufacturers. In addition, we believe that there is not currently sufficient information to develop aerodynamic performance standards on these relatively new and untried technologies. Consequently, we are adopting design-based tire technology standards for non-box trailers, as proposed. Non-box trailer manufacturers may include aerodynamic improvements in their future trailer designs, but non-box trailer aerodynamic devices cannot be used for compliance at any point in the Phase 2 program.

(ii) Aerodynamic Technologies for Box Vans

EPA collected aerodynamic test data for several tractor-trailer configurations equipped with technologies similar to common SmartWay-verified technologies. As mentioned previously, SmartWay-verified technologies are evaluated on 53-foot dry vans. However, the CO₂- and fuel consumption-reducing potential of some aerodynamic technologies demonstrated on 53-foot dry vans can be translated to refrigerated vans and box trailers of other lengths. Some fleets have opted to add trailer skirts to their refrigerated vans and 28-foot trailers and our testing included dry vans of length 53-foot, 48-foot, 33-foot, and 28-foot.³⁵¹

In order to evaluate performance and cost of the aerodynamic technologies, the agencies identified “packages” of individual or combined technologies that are being sold today on box trailers. The agencies also identified distinct performance levels (*i.e.*, bins) for these technology packages based on EPA’s aerodynamic testing. All technology packages that produce similar improvements in drag would be categorized as meeting the same bin level of performance. The agencies recognize that there are other technology options that have similar performance to those that we analyzed. We chose the technologies presented

here based on their current adoption rates and availability of test data.

The agencies are adopting a regulatory structure for box trailers with seven bins to evaluate aerodynamic performance. Note that these bins are slightly different than those proposed. We adjusted the aerodynamic bins to reflect additional data and the use of wind-averaged results. The most notable difference is that we expanded the width of the lower bins. The NPRM Bins III, IV and V were reduced to two bins. Bins V, VI, and VII are identical to the highest bins from the NPRM (NPRM bins VI, VII, and VIII). See Chapter 2.10.2.1.3 of the RIA for a complete description of the development of these bins.

In the final trailer program, Bin I represents a base trailer with no aerodynamic technologies added and a delta C_dA of zero. Bin II is intended to capture aerodynamic devices that achieve small reductions in CO₂ and fuel consumption. Some gap reducers may achieve Bin II on long dry vans, and most individual devices (*e.g.*, skirts or tails) will achieve this bin for short box vans. We expect a majority of single aerodynamic devices to perform in the range of Bins III through IV for long box vans. Combinations of devices are expected to meet Bin III for short vans and Bin V or Bin VI levels of performance for long vans. Bin VI represents the more optimized combinations of technologies on long vans. The agencies observed one device combination that met Bin VI in our aerodynamic testing and did not observe any combinations that meet Bin VII. This final level is designed to represent aerodynamic improvements that may become available in the future, including aerodynamic devices yet to be designed or approaches that incorporate changes to the design of trailer bodies. The agencies believe there is ample lead time to optimize additional existing Bin V combinations such that they can also meet Bin VI by MY 2027. However, none of the standards are predicated on the performance of Bin VII aerodynamic improvements. See Table IV–14 and accompanying text.

Table IV–5 illustrates the bin structure that the agencies are adopting as the basis for box vans to demonstrate compliance. The agencies believe these bins apply to all box vans (dry and refrigerated vans of various lengths). Although the underlying test data from EPA’s aerodynamic testing program reflect some variation due to differences in test methods, as well as differences in trailer and aerodynamic device models, the agencies believe that each of these bins covers a wide enough range

of delta C_dAs to account for the uncertainty. See RIA Chapter 2.10 for more information.

When manufacturers obtain test results, they would check the range shown in Table IV–5 for the measured C_dA value and use the corresponding input value for compliance. Note that these are wind-averaged results, as described in Chapter 2.10 of the RIA and below in Section IV.E.(3)(b)(ii). Also, the input is a threshold and not an average of the bin range. Consequently, the compliance results will be a conservative estimate of the performance of most technologies that achieve a given bin.³⁵²

TABLE IV–5—TECHNOLOGY BINS USED TO EVALUATE TRAILER BENEFITS AND COSTS

Bin	Delta C _d A	
	Measured value	Input value for compliance
Bin I	<0.10	0.0
Bin II	0.10–0.39	0.1
Bin III	0.40–0.69	0.4
Bin IV	0.70–0.99	0.7
Bin V	1.00–1.39	1.0
Bin VI	1.4–1.79	1.4
Bin VII	≥1.80	1.8

To develop the standards for box trailers, the agencies assessed the CO₂ emissions and fuel consumption impacts of the aerodynamic bins using an equation based on the GEM vehicle simulation tool. See Section II and Section IV.E. (1) for more information about GEM and Chapter 2.10.5 of the RIA for our development of the GEM-based equation. Within GEM, and reflected in the results of the equation, the aerodynamic performance of each box van subcategory is evaluated by subtracting the delta C_dA shown in Table IV–5 from the C_dA value representing a specific standard tractor pulling a trailer with no CO₂- or fuel consumption-reducing technologies (*i.e.*, a “no-control” trailer). In other words, the tractor-trailer is simulated with improvements to the baseline trailer. The agencies chose to model the no-control long box dry van using a C_dA value of 6.0 m² (the mean wind-averaged C_dA from EPA’s wind tunnel

³⁵¹ Although, as noted above, compliance testing (where required) uses either a 28 foot van or 53 foot van to simplify the compliance process.

³⁵² This is in contrast to the tractor program where manufacturers obtain absolute C_dA values in tractor aerodynamic testing. The tractor results are corrected to coastdown values before applying them to bins and obtaining a bin-average value as a compliance input. Trailers measure a delta C_dA and do not have a correction to a reference method (see Section IV.E.(3)(b)). The lower threshold approach adopted for the trailer compliance inputs limits the chance of over-predicting performance when a reference method correction is not applied.

testing). The single, short box dry vans showed lower C_{dA} values compared to its 53-foot counterpart in EPA's wind tunnel testing with an average of 5.6 m². The agencies did not test any refrigerated vans, but we assumed a refrigerated van's TRU would behave similar to a gap reducer. Our test results in Chapter 2.10.2.1.3 did not show gap reducer technologies to have a significant effect on C_{dA} and the agencies accordingly assigned the same default C_{dA} to refrigerated and dry box vans in GEM. Note that the trailer subcategories that have design standards (*i.e.*, non-box and non-aero box trailers) do not have numerical standards to meet, and do not have defaults in GEM. Table IV-6 illustrates the no-control drag areas (C_{dA}) associated with each trailer subcategory.

TABLE IV-6—DEFAULT AERODYNAMIC DRAG AREA (C_{dA}) VALUES ASSOCIATED WITH EACH (NO-CONTROL) TRAILER MODELED IN GEM

Trailer subcategory	C_{dA} (M ²)
Long Dry Van	6.0
Short Dry Van	5.6
Long Ref. Van	6.0
Short Ref. Van	5.6

Current "boat tail" devices, applied to the rear of a trailer with rear swing doors, are typically designed to collapse flat as the trailer rear doors are opened. If the tail structure can remain in the collapsed configuration when the doors are closed, the benefit of the device is lost. We requested comment on whether we should require that trailer manufacturers using such devices for compliance with these standards only use designs that automatically deploy when the vehicle is in motion. STEMCO commented that automatic deployment should not be required, since those systems are more expensive, and in their view, not necessary for the Phase 2 program. STEMCO believes that, since there is a strong economic incentive for operators to ensure that the devices are correctly deployed in order to achieve the greatest fuel cost payback, a regulatory requirement related to deployment is not needed. We generally agree, and have not included such a requirement in the final trailer program. For this analysis, we consider all boat tails to be properly deployed.

The agencies are aware that physical characteristics of some box trailers influence the technologies that can be applied. For instance, the TRUs on refrigerated vans are located at the front of the trailer, which prevents the use of current gap-reducers, either by

occupying the space that a front-end fairing would use, or by blocking air flow that the TRU needs for cooling purposes. Similarly, drop deck dry vans have lowered floors between the landing gear and the trailer axles that limit the ability to use side skirts. We discuss another example, roll-up rear doors, in Section IV.C.(1)(a) above. The agencies considered the availability and limitations of aerodynamic technologies for each trailer type evaluated in our feasibility analysis of the standards.

(b) Tire Rolling Resistance

Similar to the Phase 2 tractor and vocational vehicle programs, the agencies are adopting standards based on adoption of lower rolling resistance tires. While some box vans continue to be sold with tires of higher rolling resistances, the agencies believe most box van tires currently achieve a tire C_{RR} of 6.0 kg/ton or better. Feedback from several box trailer manufacturers indicates that the standard tires offered on their new trailers are SmartWay-verified tires (*i.e.*, C_{RR} of 5.1 kg/ton or better). An informal survey of members from the Truck Trailer Manufacturers Association (TTMA) in 2014 indicates about 85 percent of box vans sold at that time had SmartWay tires.³⁵³

The agencies evaluated two levels of tire performance for box vans beyond the baseline trailer tire rolling resistance level (TRRL) of 6.0 kg/ton. The first performance level was set at the criteria for SmartWay-verification for trailer tires, 5.1 kg/ton, which is a 15 percent reduction in C_{RR} from the baseline. As mentioned previously, several tire models available today achieve rolling resistance values well below the present SmartWay threshold. Given the multiple year phase-in of the standards, the agencies expect that tire manufacturers will continue to respond to demand for more efficient tires and will offer increasing numbers of tire models with rolling resistance values significantly better than today's typical LRR tires. In this context, we believe it is reasonable to expect a large fraction of the trailer industry could adopt tires with rolling resistances at a second performance level that will achieve an additional reduction in rolling resistance, especially in the later stages of the program. The agencies project the C_{RR} for this second level of performance to be a value of 4.7 kg/ton (a 22 percent reduction from the baseline tire).

The vast majority of box van miles occur on-road, and current LRR tire

designs are appropriate and effective for those applications. We note that current designs of LRR tires may not be appropriate for some non-box trailer types, including those that operate significantly in off-road conditions. We expect that the tire manufacturing industry will continue to expand their offerings of tire designs to additional applications. Regardless, by limiting the non-box trailer types covered by the final trailer program to those generally used in on-highway applications (tanks, flatbeds, and container chassis), the program avoids most of these potential situations.

We received comment from Michelin supporting the use of 6.0 kg/ton as the box trailer tire rolling resistance baseline, but they expressed concern that the SmartWay threshold of 5.1 kg/ton does not apply for non-box trailers, and could compromise their operation. Similarly, the Rubber Manufacturers Association indicated that a baseline of 6.0 kg/ton does not apply to non-box trailers. The agencies agree that the baseline tires for non-box trailers should have a higher rolling resistance, but we did not receive any comments that included C_{RR} data. For the analysis for the final rules, the agencies revised the baseline C_{RR} to a value of 6.5 kg/ton for non-box trailer manufacturers. The updated non-box trailer designs standards require LRR tires of 6.0 kg/ton in the first stage of the program and 5.1 kg/ton in the later years. Nowhere in the final program do we require Level 4 tires for non-box trailers.

The agencies evaluated four tire rolling resistance levels, summarized in Table IV-7, in the feasibility analysis of the following sections. It should be noted that these levels are targets for setting the stringency of the box van performance standards and rolling resistance thresholds for the non-box design standards. For compliance, box van manufacturers have the option to use tires with any rolling resistance and are not be limited to these TRRLs.

TABLE IV-7—SUMMARY OF TRAILER TIRE ROLLING RESISTANCE LEVELS EVALUATED

Tire rolling resistance level	C_{RR} (kg/ton)
Level 1 (Non-Box Baseline)	6.5
Level 2 (Box Van Baseline)	6.0
Level 3	5.1
Level 4	4.7

(c) Tire Pressure Systems

Tire pressure monitoring systems (TPMS) and automatic tire inflation systems (ATIS) are designed to address under-inflated tires. Both systems alert

³⁵³ Letter, Truck Trailer Manufacturers Association to EPA. Received on October 16, 2014. Docket EPA-HQ-OAR-2014-0827-0146.

drivers if a tire's pressure drops below its set point. TPMS are simpler and merely monitor tire pressure. Thus, they require user-interaction to reinflate to the appropriate pressure. Today's ATIS, on the other hand, typically take advantage of trailers' air brake systems to supply air back into the tires (continuously or on demand) until a selected pressure is achieved. In the event of a slow leak, ATIS have the added benefit of maintaining enough pressure to allow the driver to get to a safe stopping area. See Chapter 2.10.2.3 of the RIA for more on tire pressure systems.

The agencies proposed that ATIS be the only tire pressure system allowed to be used to meet the standards, since TPMS require action on the part of the operator. Our position at the time of the proposal was that TPMS could not sufficiently guarantee proper inflation. 80 FR 40262. However, some commenters stated that TPMS are effective in encouraging proper tire pressure maintenance, and should also be eligible as a compliance option. Commenters did not provide specific data about the overall effectiveness of TPMS. However, we are aware of the emergence of TPMS that use telematics to automatically report tire pressure data to a central contact. It is also our understanding that there is a growing recognition among fleet and individual operators of the potential value that these systems can provide to operators, so long as the operator and/or a central fleet contact take action to address cases of low tire pressures indicated by the systems. These factors have led the agencies to reconsider our approach to TPMS. As described in Section IV.B. above, we now believe that TPMS provides overall fuel consumption and CO₂ reductions, and the final program recognizes the option of TPMS as part of the compliance path for all covered trailers.

NHTSA and EPA recognize the role of proper tire inflation in maintaining optimum tire rolling resistance during normal trailer operation. Rather than require performance testing of tire pressure systems, the agencies recognize the benefits of these systems, and the program applies default reduction values for manufacturers that incorporate ATIS or TPMS into their trailer designs. Based on information available today, we believe that most tire pressure technologies and systems in typical use perform similarly.

We proposed to assign a 1.5 percent reduction in CO₂ and fuel consumption for all trailers that implement ATIS, based on information available at that

time.³⁵⁴ We did not receive any comments directly addressing the proposed reduction value. However, the agencies believed it was appropriate to align the effectiveness of tire pressure systems for tractors, trailers and vocational vehicles, and the agencies are adopting a 1.2 percent reduction for ATIS for each of these vehicle categories. As just noted, we are also adopting provisions that recognize a CO₂ and fuel consumption reduction for TPMS. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS (for example, for reasons of personal safety as well as fuel savings). However, we recognize the dependence on operator action for TPMS, and we are adopting a reduction of 1.0 percent for these systems. We have concluded that the use of these systems can consistently ensure that tire pressure and tire rolling resistance are maintained. Sections III.D.(1)(b) and V.C.(1)(a) also discuss the overall Phase 2 program's treatment of both types of tire pressure systems for tractors and vocational vehicles, respectively.

We selected the standards for most box vans with the expectation that a high rate of adoption of ATIS will occur during all years of the phase-in of the program, and that manufacturers of non-aero vans, and non-box trailers will install either TPMS or ATIS, as well as LRR tires, to comply with the design-based tire standards.

In the performance-based compliance approach to full- and partial-aero box vans, the program incorporates a small discount in the value of TPMS in the compliance equation as compared to ATIS, to reflect the inherent user interaction required for TPMS to be effective. In the design-based compliance approach for non-aero vans and non-box trailers, manufacturers may comply by using either TPMS or ATIS, which in that case are valued equally. See Section IV.D.(2)(d) below for discussion of our estimates of the degree of adoption of tire pressure systems prior to and at various points in the phase-in of the proposed program.

(d) Weight Reduction

As proposed, the trailer program provides manufacturers the option of complying through the substitution of specified lighter-weight components that can be clearly isolated from the trailer as a whole. In the proposal, the agencies identified several conventional components with lighter-weight substitutes that are currently available

(e.g., substituting conventional dual tires mounted on steel wheels with wide-based single tires mounted on aluminum wheels). 80 FR 40262. Several commenters provided additional component suggestions, with information about their typical associated weight reductions. The component substitutions we have included in the final program, and the weight savings that we are associating with each component, are presented in the RIA Chapter 2.10.2.4 and 40 CFR 1037.515. The agencies have identified 12 common trailer components for which lighter weight options are currently available (see 40 CFR 1037.515).^{355 356 357 358} Manufacturers that adopt these technologies and choose to use them as part of their compliance strategy sum the associated weight reductions and apply those values in the GEM-based compliance equation (see Section IV.E.(2)(a)). We believe that the initial cost of these component substitutions is currently substantial enough that only a relatively small segment of the industry has adopted these technologies today.

There is no clear "baseline" for current trailer weight against which lower-weight designs could be compared for regulatory purposes. For this reason, the agencies do not believe it is appropriate or fair across the industry to apply overall weight reductions toward compliance using a universal baseline trailer. However, the agencies do believe it is appropriate to give a manufacturer credit for overall weight reduction achieved in their own product line. In the final program, we are clarifying that manufacturers of box trailers with significant weight reductions have the option of using our off-cycle credit process to compare overall weight reduction of future trailers using an appropriate baseline from their own production. This process allows manufacturers to do a comparison of their new trailer to a previous model to quantify the weight reduction improvements. Manufacturers wishing to go this route should contact

EPA in advance to discuss appropriate test procedures. More information about the off-cycle process can be found in Section IV.E.(5)(d) and in 40 CFR 1037.610 or 49 CFR 535.7. Note that non-box trailers and non-aero box vans have design standards that are limited to adoption of lower rolling resistance tires and tire pressure systems, and do not include weight reduction as part of their simplified compliance demonstration.

The agencies recognize that when weight reduction is applied to a trailer, some operators will replace that saved weight with additional payload. To account for this in the average vehicle represented by EPA's GEM vehicle simulation tool, it is assumed that one-third of any weight reduction will be applied to the payload. Wabash suggested that the agencies reconsider the distribution of weight between payload and trailer weight when modeling weight reduction, expressing concern that the reduction was not receiving appropriate credit in the program. Although the simulated vehicle in GEM only receives 2/3 of the weight reduction applied, the model calculates CO₂ emissions and fuel consumption on a per-ton-mile basis by dividing by the payload, which now includes the extra one-third from weight reduction. Dividing by a larger payload results in lower CO₂ and fuel consumption values.³⁵⁹

For 53-foot vans simulated in GEM (and thus, for the GEM-based equation), it takes a weight reduction of nearly 1,000 pounds before a one percent fuel savings is achieved. The impact of the same 1000 pounds is slightly greater for shorter vans, due to their lower overall

weight, but the effectiveness of weight reduction is still relatively low compared to the effectiveness of many aerodynamic technologies. In addition, large material substitutions can be costly. The agencies thus believe that few trailer manufacturers will apply weight reduction solely as a means of achieving reduced fuel consumption and CO₂ emissions. Therefore, we are adopting standards that could be met without reducing weight—that is, the feasible compliance path set out by the agencies for this program does not assume weight reduction as a compliance avenue. However, as discussed here, the final program includes the option for box trailer manufacturers to apply weight reduction to some of their trailers as part of their compliance strategy.

(2) Effectiveness, Adoption Rates, and Costs of Technologies for the Trailer Standards

The agencies evaluated the technologies above as they apply to each of the trailer subcategories. The next sections describe the effectiveness, adoption rates and costs associated with these technologies. The effectiveness and adoption rate projections were used to derive these standards.

(a) No-Control Default Tractor-Trailer Vehicles in GEM (Box Van Standards Only)

The regulatory purpose of EPA's heavy-duty vehicle compliance tool, GEM, is to combine the effects of trailer technologies through simulation so that they can be expressed as g/ton-mile and gal/1000 ton-mile and thus avoid the

need for direct testing of each trailer being certified. All of the standards for box vans (with the exception of non-aero box vans, which have design standards) use an equation derived from GEM to demonstrate compliance. The trailer program has separate performance standards for each box van subcategory (again, with the exception of non-aero box vans) and each of these subcategories is modeled as a tractor-trailer combination that we believe reflects the average physical characteristics and use pattern of vans in that subcategory. Long vans are pulled by sleeper cab tractors and use the long-haul drive cycle weightings. Short vans are pulled by day cabs and have the short-haul drive cycle weightings. Short vans also have a lighter payload and overall vehicle weight compared to their longer counterparts.

Table IV–8 highlights the relevant vehicle characteristics for the no-control default of each subcategory (*i.e.*, zero CO₂- or fuel consumption reducing technologies installed). Baseline trailer tires are used, and the drag area, which is a function of the aerodynamic characteristics of both the tractor and trailer, is set to the values shown previously in Table IV–6. Weight reduction and tire pressure systems are not applied in these default vehicles. Chapter 2.10 of the RIA provides a detailed description of the development of these default tractor-trailers. Note that the agencies proposed to use Class 8 tractors for all default tractor-trailer vehicles. However, we are adopting the final standards based on 4x2 Class 7 tractors for short box vans.

TABLE IV–8—CHARACTERISTICS OF THE NO-CONTROL DEFAULT TRACTOR-TRAILER VEHICLES IN GEM

Trailer length	Dry van		Refrigerated van	
	Long	Short	Long	Short
Standard Tractor:				
Class	Class 8	Class 7	Class 8	Class 7.
Cab Type	Sleeper	Day	Sleeper	Day.
Roof Height	High	High	High	High.
Axle Configuration	6 x 4	4 x 2	6 x 4	4 x 2.
Engine	2018 MY 15L, 455 HP	2018 MY 11L, 350 HP	2018 MY 15L, 455 HP	2018 MY 11L, 350 HP.
Steer Tire RR (kg/ton)	6.54	6.54	6.54	6.54.
Drive Tire RR (kg/ton)	6.92	6.92	6.92	6.92.
Drag Area, C _d A (m ²)	6.0	5.6	6.0	5.6.
Number of Trailer Axles	2	1	2	1.
Trailer Tire RR (kg/ton)	6.00	6.00	6.00	6.00.
Total Weight (kg)	31978	18306	33778	20106.
Payload (tons)	19	10	19	10.

Distribution in Response to Public Comments from Wabash National Corporation,” June 18, 2016.

TABLE IV-8—CHARACTERISTICS OF THE NO-CONTROL DEFAULT TRACTOR-TRAILER VEHICLES IN GEM—Continued

Trailer length	Dry van		Refrigerated van	
	Long	Short	Long	Short
Transient Driving	5%	19%	5%	19%.

(b) Effectiveness of Technologies

As already noted, the agencies recognize trailer improvements via four performance parameters: Aerodynamic

drag reduction, tire rolling resistance reduction, the adoption of tire pressure systems, and weight-reducing strategies. Table IV-9 summarizes the performance

levels the agencies evaluated for each of these parameters based on the technology characteristics outlined in Section IV.D.(1).

TABLE IV-9—PERFORMANCE PARAMETERS FOR THE TRAILER PROGRAM

Aerodynamics (Delta C _d A, m ²):	
Bin I	0.0.
Bin II	0.1.
Bin III	0.4.
Bin IV	0.7.
Bin V	1.0.
Bin VI	1.4.
Bin VII	1.8.
Tire Rolling Resistance (C _{RR} , kg/ton):	
Tire Level 1	6.5.
Tire Level 2	6.0.
Tire Level 3	5.1.
Tire Level 4	4.7.
Tire Inflation System (% reduction):	
ATIS	1.2.
TPMS	1.0.
Weight Reduction (lb):	
Weight	1/3 added to payload, remaining reduces overall vehicle weight.

These performance parameters have different effects on each trailer subcategory due to differences in the simulated trailer characteristics. Table IV-10 shows the agencies' estimates of the effectiveness of each parameter for

the four box van types. Each technology was evaluated using the baseline parameter values for the other technology categories. For example, each aerodynamic bin was evaluated using the baseline tire (6.0 kg/ton) and

the baseline weight reduction option (zero pounds). The table shows that aerodynamic improvements offer the largest potential for CO₂ emissions and fuel consumption reductions, making them relatively effective technologies.

TABLE IV-10—EFFECTIVENESS (PERCENT CO₂ EMISSIONS AND FUEL CONSUMPTION) OF TECHNOLOGIES FOR BOX VANS IN THE TRAILER PROGRAM

Aerodynamics	Delta C _d A (m ²)	Dry van		Refrigerated van	
		Long (%)	Short (%)	Long (%)	Short (%)
Bin I	0.0	0	0	0	0
Bin II	0.1	1	1	1	1
Bin III	0.4	3	3	3	3
Bin IV	0.7	5	5	5	5
Bin V	1.0	7	7	7	7
Bin VI	1.4	9	10	9	10
Bin VII	1.8	12	13	12	13
Tire Rolling Resistance	C _{RR} (kg/ton)	Dry van		Refrigerated van	
		Long	Short	Long	Short
Level 1	6.5				
Level 2	6.0	0	0	0	0
Level 3	5.1	-2	-1	-2	-1
Level 4	4.7	-3	-2	-3	-2
Weight Reduction	Weight (lb)	Dry van		Refrigerated van	
		Long	Short	Long	Short
Baseline	0	0	0	0	0

TABLE IV–10—EFFECTIVENESS (PERCENT CO₂ EMISSIONS AND FUEL CONSUMPTION) OF TECHNOLOGIES FOR BOX VANS IN THE TRAILER PROGRAM—Continued

Aerodynamics	Delta C _d A (m ²)	Dry van		Refrigerated van	
		Long (%)	Short (%)	Long (%)	Short (%)
Option 1	100	0	0	0	0
Option 2	500	1	1	1	1
Option 3	1000	1	2	1	2
Option 4	2000	2	4	2	4

(c) Baseline Tractor-Trailer To Evaluate Benefits and Costs

In order to evaluate the benefits and costs of the final standards for each of the ten subcategories, it is necessary to establish a reference point for comparison. As mentioned previously, the technologies described in Section IV.D.(1) exist in the market today, and their adoption is driven by available fuel savings as well as by the voluntary SmartWay Partnership and California's tractor-trailer requirements. For these rules, the agencies identified baseline tractor-trailers for each trailer subcategory based on the technology adoption rates we project would exist in MY 2018 if this trailer program was not implemented.

CARB's comments noted the informal survey of TTMA members provided in letter from TTMA to EPA in 2014 regarding current adoption rates of several technologies. CARB suggested that our proposed baseline adoption rates did not reflect the data in that letter.³⁶⁰ We have reassessed available

data and we believe that higher baseline rates are more appropriate, and have made corresponding changes in our analysis. First, we created a separate baseline for box vans that qualify as full-aero, box vans that qualify as partial-aero, and box vans that qualify as non-aero. Because of the challenges of installing effective aerodynamic devices, market forces are not likely to significantly drive adoption of CO₂- and fuel-consumption reducing technologies for trailers with work performing equipment (e.g., lift gates), and we are projecting zero adoption of the technologies in the baselines for partial- and non-aero box vans before the start of this program. Similarly, we assume that there will be zero adoption of these technologies for non-box trailers in the baseline. We updated the baseline tire rolling resistance level for non-box trailers to reflect the lower 6.5 kg/ton value in response to RMA's comment that these trailers have different operational characteristics and should

not have the same baseline tires as box vans (see Section IV.D.(1)(b) above).

TTMA's survey indicated that 35 percent of long vans and less than 2 percent of vans under 53-foot in length include aerodynamic devices, and over 80 percent have adopted lower rolling resistance tires. The agencies believe the trailers for which manufacturers have adopted these technologies are likely to be trailers that would qualify as "full-aero" vans, and we adjusted our baselines to reflect these values. Our baseline assumes that aerodynamics would increase to 40 percent adoption for full-aero long vans (dry and refrigerated) and 5 percent for full-aero short vans by 2018 without the Phase 2 standards. We also assume adoption of lower rolling resistance tires (Level 1) will increase to 90 percent and ATIS to 45 percent in the baseline. We held these adoption rates constant throughout the timeframe of the rules. Table IV–11 summarizes the updated baseline trailers for each trailer subcategory.

TABLE IV–11—ESTIMATED ADOPTION RATES AND AVERAGE PERFORMANCE PARAMETERS FOR THE FLAT BASELINE TRAILERS FOR MY 2018 AND LATER

Technology	Long vans	Short vans	All partial-aero, non-aero vans	All non-box trailers

<i>Weight (lb)^b.</i>				

Notes:

A blank cell indicates a zero value.

^a Combines adoption rates with performance levels shown in Table IV-9.^b Weight reduction was not projected for the baseline trailers.

Also shown in Table IV-11 are average aerodynamic performance (delta C_dA), average tire rolling resistance (C_{RR}), and average reductions due to use of tire pressure systems and weight reduction for each reference trailer. These values indicate the performance of theoretical average tractor-trailers that the agencies project would be in use in 2018 if no federal regulations were in place for trailer CO_2 and fuel consumption. The average tractor-trailer vehicles serve as baselines for each trailer subcategory.

Because the agencies cannot be certain about future trends, we also

considered a second baseline. This dynamic baseline reflects the possibility that, absent a Phase 2 regulation, there would be continuing adoption of aerodynamic technologies in the long box trailer market after 2018 that reduce fuel consumption and CO_2 emissions. This case assumes the research funded and conducted by the federal government, industry, academia and other organizations would, after 2018, result in the adoption of additional aerodynamic technologies beyond the levels required to comply with existing regulatory and voluntary programs. One example of such research is the

Department of Energy SuperTruck program which has a goal of demonstrating cost-effective measures to improve the efficiency of Class 8 long-haul freight trucks by 50 percent by 2015.³⁶¹ This baseline assumes that by 2040, 75 percent of new full-aero long vans would be equipped with SmartWay-verified aerodynamic devices. The agencies project that the lower rolling resistance tires and ATIS adoption would remain constant. Table IV-12 shows the agencies' projected adoption rates of technologies in the dynamic baseline.

^a Combines adoption rates with performance levels shown in Table IV-9.^b Weight reduction was not projected for the baseline trailers.

The agencies applied the vehicle attributes from Table IV-8 and the average performance values from Table

IV-11 in the Phase 2 GEM vehicle simulation to calculate the CO_2 emissions and fuel consumption

performance of the baseline tractor-trailers. The results of these simulations are shown in Table IV-13. We used

³⁶¹ Daimler Truck North America. SuperTruck Program Vehicle Project Review. June 19, 2014. Docket EPA-HQ-OAR-2014-0827.

these CO₂ and fuel consumption values to calculate the relative improvements that will occur over time with a regulatory program. Note that the large difference between the per ton-mile values for long and short trailers is due primarily to the large difference in

assumed payload (19 tons compared to 10 tons) and the small difference between dry and refrigerated vans of the same length are due to differences in vehicle weight because of the 1800 pounds added to the simulated refrigerated vans to account for the TRU

(see the vehicle characteristics of the simulated tractor-trailers Table IV–8). The alternative baseline shown in Table IV–12 mainly impacts the long-term projections of benefits beyond 2027, which are analyzed in Chapters 5–7 of the RIA.

TABLE IV–13—CO₂ EMISSIONS AND FUEL CONSUMPTION RESULTS FOR THE BASELINE TRACTOR-TRAILERS

Length	Full-aero dry van		Full-aero refrigerated van		Partial-aero dry van		Partial-aero refrigerated van	
	Long	Short	Long	Short	Long	Short	Long	Short
CO ₂ Emissions (g/ton-mile)	83.2	126.5	84.9	130.3	86.1	128.5	87.9	132.4
Fuel Consumption (gal/1000 ton-miles)	8.17289	12.42633	8.33988	12.79961	8.45776	12.62279	8.63458	13.00589

(d) Projected Technology Adoption Rates for the Trailer Standards

The agencies developed their performance and design standards based on projected adoption rates of certain technologies. This section describes how these adoption rates were applied for each of the trailer subcategories.

(i) Aerodynamic and Tire Technologies for Full- and Partial-Aero Box Vans

As described in Section 0, the agencies evaluated several alternatives for the trailer program. Based on our analysis and comments received, the agencies are adopting standards consistent with the agencies' respective statutory authorities. The agencies proposed alternatives that were based on the use of averaging and the technology adoption rates for those alternatives at proposal reflected the use of averaging. As noted in Section IV.B., we received nearly unanimous, persuasive comments from the trailer industry opposing averaging and the agencies reconsidered the use of averaging in the early years of the program. The agencies designed the trailer program to have no averaging in MY 2018 through MY 2026. In those years, all box vans sold must meet the standards using any combination of available technologies. In MY 2027, when the trailer manufacturers are more comfortable with compliance and the industry is more familiar with the technologies, trailer manufacturers will have the option to use averaging to meet the standards. See Section IV.E.(5)(b) below for additional information about averaging.

Table IV–14 and Table IV–15 present sets of assumed adoption rates for aerodynamic, tire, and tire pressure technologies that a manufacturer could apply to meet the box van standards. Since averaging would not be allowed for MY 2018–MY 2026, the adoption rates consist of the combination of a

single aerodynamic bin (not reflecting any averaging of aerodynamic controls), tire rolling resistance level, and tire pressure system. As mentioned previously, manufacturers can choose other combinations to meet the standards. Chapter 2.10 of the RIA shows several examples of alternative compliance pathways.

The adoption rates in Table IV–14 begin with all full-aero long box vans achieving current SmartWay-level aerodynamics (Bin III) in MY 2018 with a stepwise progression to achieving Bin V in 2024. The adoption rates for full-aero short box vans in Table IV–15 assume no adoption of aerodynamic devices in MY 2018, adoption of single aero devices in MY 2021, and combinations of devices by MY 2024. Although the shorter lengths of these trailers can restrict the design of aerodynamic technologies that fully match the SmartWay-like performance levels of long boxes, we nevertheless expect that trailer and device manufacturers will continue to innovate skirt, under-body, rear, and gap-reducing devices and combinations to achieve improved aerodynamic performance on these shorter trailers.

The adoption rates in MY 2018–MY 2026 are projected to be 100 percent for each technology, instead of an industry average seen in other vehicle sectors in the Phase 2 program. Since we are not considering averaging during those years, each set of adoption rates is one example of how an individual trailer in each subcategory could comply. Through MY 2026, the standards are based on technologies that exist today. We evaluated one technology in our aerodynamic test programs that met Bin VI levels of performance for long vans, suggesting that this bin can be met with combinations of existing aerodynamic technologies, but none of our tested technologies that met Bin IV levels of performance for short vans. We could

not justify standards based on 100 percent adoption of those levels of performance as a final step in our progression of stringency. However, the industry has made great progress toward improving trailer aerodynamics in recent years and are continuing to optimize these technologies. Although we are not projecting fundamentally new technologies for trailers, we do believe aerodynamic performance will evolve in the trailer industry as a result of this rulemaking. Based on the recent rate of improvement, the agencies believe that there is ample lead time to optimize additional existing Bin V and Bin III combinations such that they can also meet Bins VI and IV by MY 2027 and it is reasonable to project that more than half of these full-aero capable trailers will have aerodynamic improvements greater than what is possible with today's technologies. Our projected aerodynamic improvements in MYs 2027 and later reflect this performance potential.

The MY 2027 full-aero box van standards are based on an averaging program.³⁶² We cannot predict what technologies or trailer designs may be adapted to meet this level of aerodynamic performance, but an averaging program incentivizes manufacturers to develop advanced designs with the benefit that not all trailers in their production have to meet the same level of performance. The gradual increase in assumed adoption of aerodynamic technologies throughout the phase-in to the MY 2027 standards recognizes that even though many of the technologies are available today and technologically feasible throughout the phase-in period, adoption of more advanced technologies will likely take time. The adoption rates we are

³⁶² No averaging is allowed for partial-aero box van reduced standards, or the design-based standards for non-aero box vans and non-box trailers.

projecting in the interim years and the standards that we developed from these rates represent steady and reasonable improvement in aerodynamic performance.

We expect manufacturers of all box vans will adopt tires such as SmartWay-verified trailer tires (Level 3) to meet the standards in MY 2018 and will adopt tires with even lower rolling resistance

tires (represented as Level 4) as they become available by MY 2021 and later years and as fleet experience with these tires develops.

In establishing standard stringency, the agencies are also assuming that all box vans will adopt ATIS throughout the program, though manufacturers have the option to install TPMS if they would prefer to make up the difference in

effectiveness using other technologies. As mentioned previously, the agencies did not include weight reduction in their technology adoption projections, but certain types of weight reduction could be used as part of a compliance pathway, as discussed in Section IV.D.(1)(d) IV.D.(1)(d) above.

^a The majority of short box trailers are 28 feet in length. We recognize that they are often operated in tandem, which limits the technologies that can be applied (for example, boat tails).

^b Combines projected adoption rates with performance levels shown in Table IV–9.

^c This set of adoption rates did not apply any assumed weight reduction to meet these standards for these trailers.

The agencies proposed that the partial-aero box vans would track with the full-aero van standards until MY 2024. 80 FR 40257. Wabash commented that partial-aero box vans should be exempt starting in MY 2021 since partial-aero vans cannot use multiple devices. The agencies reconsidered the proposed partial-aero standards and

recognize that it would likely be difficult to meet the proposed MY 2024 standards without the use of multiple devices and yet partial-aero trailers, by definition, are restricted from using multiple devices. For these reasons, the agencies redesigned the partial-aero standards, such that trailers with qualifying work-performing equipment

can meet standards that would be achievable with the use of a single aerodynamic device throughout the program, similar to the MY 2018 standards. The partial-aero standards do, however, increase in stringency slightly in MY 2021, to reflect the broader use of improved lower rolling resistance tires.

Notes:

A blank cell indicates a zero value.

^a Combines projected adoption rates with performance levels shown in Table IV–9.

^b This set of adoption rates did not apply weight reduction to meet these standards for these trailers.

The adoption rates shown in these tables are one set of many possible combinations that box trailer manufacturers could apply to achieve the same average stringency. If a manufacturer chose these adoption rates, a variety of technology options exist within the aerodynamic bins, and several models of LRR tires exist for the levels shown. Alternatively, technologies from other aero bins and tire levels could be used to comply. It should be noted that since the standards for box vans are all performance-based, box van manufacturers are not limited to specific aerodynamic and tire technologies in their compliance choices. Certain types of weight reduction, for example, may be used as part of a compliance pathway. See RIA Chapter 2.10.2.4.1 for other example compliance pathways that include weight reduction.

Similar to our analyses of the baseline cases, the agencies derived a single set of performance parameters for each subcategory by weighting the performance levels included in Table

IV–9 by the corresponding adoption rates. These performance parameters represent a compliant vehicle for each trailer subcategory and are presented as average values in the Table IV–14 through Table IV–16.

(ii) Tire Technologies for Non-Aero Box Vans and Non-Box Trailers

Neither non-aero vans (*i.e.*, those with two or more work-related special components), nor non-box trailers are shown in the tables above. This is because we are adopting design-based (*i.e.*, technology-based) standards for these trailers, not performance-based standards. Manufacturers of these trailers do not need to use aerodynamic technologies, but they need to install the lower rolling resistance tires and tire pressure systems established by this program (see Section IV.C.(2)). Compared to manufacturers that needed aerodynamic technologies to comply, the approach for non-aero box trailers and non-box trailers results in a significantly lower compliance burden for manufacturers by reducing the

amount of tracking and eliminating the need to calculate a compliance value (see Section IV.E.). The agencies are adopting these design standards, which can be assumed to be 100 percent adoption, in two stages. In MY 2018, the non-box trailer standards require manufacturers to use tires meeting a rolling resistance of Level 2 or better and to install tire pressure systems. In MY 2021, non-box trailers standards require tire pressure systems and LRR tires at Level 3 or better. Non-aero box vans, which we believe are largely at a baseline rolling resistance Level 2 today, require tire pressure monitoring systems with Level 3 tires in MY 2018 and Level 4 tires in MY 2021 and later.

We received comment that manufacturers were concerned about the cost and availability of ATIS for the trailer industry. Still, based on comments about TPMS and further evaluations by the agencies, we are including TPMS as an additional option for tire pressure systems in the trailer program, as discussed in Section IV.D.(1)(c) above. Non-aero vans and

non-box trailers are compliant if they have appropriate lower rolling resistance tires and either TPMS or ATIS.

(e) Derivation of the Trailer Standards

The agencies applied the average performance parameters from Table IV–14 and Table IV–15 as input values to the GEM vehicle simulation to derive the HD Phase 2 fuel consumption and CO₂ emissions standards for each long and short full-aero box van subcategory. These full-aero van standards are shown

in Table IV–17. Similarly, the average performance parameters from Table IV–16 were used to calculate the partial-aero van standards shown in Table IV–18. The design standards for non-box trailer and non-aero box van are summarized in Table IV–19.

Over the four stages of the trailer program, the full-aero box vans longer than 50 feet are projected to reduce their CO₂ emissions and fuel consumption by two percent, five percent, seven percent and nine percent compared to their average baseline cases in Table IV–13.

Full-aero box vans 50-feet and shorter will achieve reductions of one percent, two percent, four percent and six percent compared to their average baseline cases. The partial-aero long and short box van standards will reduce CO₂ and fuel consumption by six percent and four percent, respectively, by MY 2021. The tire technologies used on non-box and non-aero box trailers are projected to provide reductions of two percent in the first stage and three percent in MY 2021 and later.

TABLE IV–17—STANDARDS FOR FULL-AERO BOX VANS

Model year	Subcategory	Dry van		Refrigerated van	
	Length	Long	Short	Long	Short
2018–2020	EPA Standard (CO ₂ Grams per Ton-Mile)	81.3	125.4	83.0	129.1
	Voluntary NHTSA Standard (Gallons per 1,000 Ton-Mile)	7.98625	12.31827	8.15324	12.68173

2021+	EPA Standard (CO ₂ Grams per Ton-Mile)	80.6	123.7	82.3	127.5
	NHTSA Standard (Gallons per 1,000 Ton-Mile)	7.91749	12.15128	8.08448	12.52456

TABLE IV–19—DESIGN-BASED TIRE STANDARDS FOR NON-BOX TRAILERS AND NON-AERO BOX VANS

Model year	Tire technology	Non-box trailers	Non-aero box vans
2018–2020	Tire Rolling Resistance Level (kg/ton)	≤6.0	≤5.1
	Tire Pressure System	TPMS or ATIS	TPMS or ATIS
2021+	Tire Rolling Resistance Level (kg/ton)	≤5.1	≤4.7
	Tire Pressure System	TPMS or ATIS	TPMS or ATIS

(f) Technology Costs for the Trailer Standards

The agencies evaluated the incremental technology costs for 53-foot dry and refrigerated vans and 28-foot dry vans. (As explained above, we believe these length trailers are representative of the majority of trailers in the long and short box van subcategories, respectively.) We identified costs for each technology package and projected the costs for each year of the program. A summary of the technology costs is included in Table

IV–20 through Table IV–23 for MYs 2018 through 2027, with additional details available in the RIA Chapter 2.12. Costs shown in the following tables are for the specific model year indicated and are incremental to the average baseline costs, which includes some level of adoption of these technologies as shown in Table IV–13. Therefore, the technology costs in the following tables reflect the average cost expected for each of the indicated trailer classes across the fleet. Note that these costs do not represent actual costs for the individual components because they

are relative to the costs of the MY 2018 baselines which are expected due to market-driven adoption of the technologies. For more on the estimated technology costs exclusive of adoption rates, refer to Chapter 2.12 of the RIA. These costs include indirect costs via markups and reflect lower costs over time due to learning impacts. For a description of the markups and learning impacts considered in this analysis and how technology costs for other years are thereby affected, refer to Chapter 7 of the RIA.

TABLE IV-20—TRAILER TECHNOLOGY INCREMENTAL COSTS IN THE 2018 MODEL YEAR
[2013\$]

(3) Consistency of the Trailer Standards With the Agencies' Statutory Obligations

The agencies have determined that the standards presented in the Section IV.C.(2), are the maximum feasible and appropriate under the agencies' respective authorities, considering lead time, cost, and other factors. The agencies' decisions on the stringency and timing of the trailer standards focused on available technology and the consequent emission reductions and fuel efficiency improvements associated with use of the technology, while taking into account the circumstances of the trailer manufacturing sector. Trailer manufacturers are subject to first-time emission control and fuel consumption regulation under the trailer standards.

These manufacturers are in many cases small businesses, with limited resources to master the mechanics of regulatory compliance. Thus, the agencies are providing ample and reasonable time for trailer manufacturers to become familiar with the requirements and the new compliance regime.

The stringency of the standard is predicated on more widespread deployment of tire technologies that are already in commercial use and existing aerodynamic devices combinations that we believe will be further optimized in the near-term. The availability, feasibility, and level of effectiveness of these technologies are well-documented. In developing the standards, we also took into account not just the capabilities of the technologies,

but also how the use of these technologies is likely to expand under the trailer program, considering factors like degree of market penetration over time and the effect of different operational patterns for different trailer types (Section IV.D.(2) above). For example, some commenters point out that trailers operating at lower speeds will achieve smaller CO₂ and fuel consumption reductions than they will at highway speeds. The agencies acknowledge this fact, and account for a fraction of trailer operation at slower speeds. All long box vans are evaluated with 5 percent of their miles at low speed operation and all short vans are evaluated with 17 percent low speed miles. While we cannot predict individual trailer use, we believe these

values are a reasonable estimate of an industry average.³⁶³ Our analysis in RIA Chapter 2.10.2.1.1 shows that skirts will provide short trailers with at least 1 percent improvement and long trailers with at least 4 percent improvement at 55 mph. We expect most trailers spend at least some of their miles at 55 mph or faster in use and will gain similar benefits during those speeds. We also show that even trailers operating under fully transient conditions (combining slower and faster operation) will experience a small improvement from use of trailer skirts.

The agencies do not believe that there is any issue of technological feasibility of the levels of the standards and the time line for implementing them in the final trailer program. The agencies considered cost and the sufficiency of lead-time, including lead-time not only to deploy technological improvements, but, as just noted, also for this industry sector to assimilate for the first time the compliance mechanisms of the trailer program.

The highest cost shown in Table IV–23 is associated with the standard for long dry vans. We project that the average cost per trailer to meet the MY 2027 standards for these trailers will be about \$1,400, which is less than 10 percent of the cost of a new dry van trailer (estimated to be about \$20,000). Other trailer types have lower projected technology costs, and many have higher purchase prices. As a result, we project that the per-trailer costs for all trailers covered in this regulation will be less than 10 percent of the cost of a new trailer.

The agencies regard these costs as reasonable. We project that most customers will rapidly recover the initial cost of these technologies due to the associated fuel savings, usually in two years. As discussed in Section IX.M and RIA Chapter 7.2.4, this payback is for tractors and trailers together, and includes both long and short-haul. This payback period is generally considered reasonable in the trailer industry for investments that reduce fuel consumption.³⁶⁴ Although longer paybacks will occur for some trailers, we do not project that any trailers will achieve lifetime fuel savings less than

the cost of the technologies. In addition, the agencies estimate the cost per metric ton of CO₂e reduction without considering fuel savings to be \$36 for tractor-trailers in 2030 which compares favorably with the levels of cost effectiveness the agencies found to be reasonable for light duty trucks.³⁶⁵

The agencies believe these technologies can be adopted at the projected rates within the lead time provided in the trailer program, as discussed above in Section IV.C.(4) above.

(4) Alternative Standards and Feasibility That the Agencies Considered

As discussed in Section X of the NPRM, the agencies evaluated five regulatory alternatives representing different levels of stringency for the Phase 2 program. See 80 FR 40273. A wide range of stakeholders commented on the proposed (Alternative 3) standards and the other alternatives that we discussed, and our final standards reflect our consideration of all of those comments.

Comments on our proposed standards (Alternative 3) and the alternatives we presented generally fell into three categories: (1) Commenters supporting Alternative 1; *i.e.*, generally advocating no mandatory standards and a continuation of today's voluntary SmartWay regime and; (2) Commenters preferring the proposed Alternative 3 standards and timeline to the standards of Alternative 4; and (3) Commenters supporting the more stringent standards and timeline of Alternative 4, Alternative 5, or of other more stringent potential programs.

Commenters including the TTMA, Utility, and Stoughton stated their belief that no mandatory standards are necessary; however, they did not provide information to show that market forces at work today will achieve the clear potential for the industry to reduce CO₂ and fuel consumption in the near- and longer-term future. The agencies have concluded that a program involving no or minimal mandatory requirements would not be appropriate or meet our statutory requirements.

As discussed previously, the agencies believe that our final trailer standards are appropriate under the Clean Air Act and are the maximum feasible standards under the EISA. In developing the proposal and the final rule, we considered standards that would be more stringent or would become effective in an earlier model year than

the proposed Alternative 3 standards and timeline. Several commenters stated that a still more stringent program should be finalized, including information about current and potential future trailer aerodynamic technologies. Commenters including CARB, NACAA, NRDC, ICCT, UCS, and STEMCO supported the standards we presented for Alternative 4 in the proposal (essentially the pull ahead of the MY 2027 standards) in the proposal. In addition, some of the commenters made the additional suggestion that the agencies should anticipate that manufacturers will incorporate a modest degree of Bin VIII technologies—*i.e.*, two bins higher than any performance demonstrated in our aerodynamic testing—in the later stages of the program. EDF supported a program of even greater stringency, supporting Alternative 5 standards (advanced aerodynamic technologies on all box vans, aerodynamic technologies on some non-box trailers, and tire technologies on all non-box trailers) on the Alternative 4 timeline. The Center for Biological Diversity (CBD) did not specifically comment on the alternatives presented in the proposal, but supported a program that would result in significantly more stringent standards (based, for example, on integrated tractor and trailer technologies, such as in the SuperTruck demonstration program). Great Dane, Wabash, ATA, and the International Foodservice Distributors Association expressed concerns that a program of the stringency and timeline of Alternative 4 would have negative consequences, including requiring trailer manufacturers to adopt less-tested technology.

Where commenters provided relevant data and information, the agencies made adjustments to the final program accordingly. For example, as noted in Section IV.C.(1) and Section IV.D.(2) previously, information from the industry was helpful in the decision to limit the non-box trailer program to tanks, flatbeds, and container chassis. Also, partially in response to information we received in comments, we slightly reduced the proposed stringency for partial-aero vans to better reflect their aerodynamic limitations. Also, while not a direct change to the stringency of the standards, the program limits averaging to the final stage of the program to allow van manufacturers more time to become familiar with the compliance processes and the industry to gain confidence in the technologies. Overall, the final standards are slightly more stringent than proposed, based on

³⁶³ Memorandum to Docket EPA–HQ–OAR–2014–0827, “Comparison of GEM Drive Cycle Weightings and Fleet Data Provided by Utility Trailer Manufacturing Co. in Public Comments”, July 2016.

³⁶⁴ Roeth, Mike, et al. “Barriers to Increased Adoption of Fuel Efficiency Technologies in Freight Trucking,” July 2013. International Council for Clean Transportation. Available here: http://www.theicct.org/sites/default/files/publications/ICCT-NACFE-CSS_Barriers_Report_Final_20130722.pdf.

³⁶⁵ See RIA Chapter 7.2.5 and Memo to Docket “Tractor-Trailer Cost per Ton Values,” July 2016. EPA–HQ–OAR–2014–0827.

an expectation of earlier adoption of more efficient lower rolling resistance tires for all subcategories, and a strengthened the full-aero van program that includes greater adoption of advanced aerodynamics in the final stage.

Based on this analysis and as informed by the comments, we believe that the final standards in the program, slightly revised from the proposed Alternative 3 standards, are appropriate and represent the maximum feasible standards. In contrast, we believe that the accelerated timeline of Alternative 4 may cause technologies to prematurely enter the market, leading to unnecessary costs and compliance burdens that would not be appropriate for this newly regulated industry. Standards similar to or more stringent than those we evaluated for Alternative 5 would require CO₂ and fuel consumption reductions that may well not be technologically achievable, even with fundamental changes to the industry. Nor did the commenters present any information as to how advanced aerodynamic technologies (Bins VII and VIII) could be developed and reliably brought to market at reasonable cost within the lead time of the Phase 2 program. On the basis of what we know today, the agencies are unable to show a pathway for the industry to achieve such additional improvements, at least without the potential for major disruptions to the industry due to requiring, for example, fundamental changes to trailer design and construction, or impractical levels of tractor-trailer integration.

E. Trailer Standards: Compliance and Flexibilities

As with other EPA motor vehicle programs, trailer manufacturers must annually obtain a certificate of conformity from EPA before introducing into commerce new trailers subject to the new trailer CO₂ and fuel consumption standards. See CAA section 206(a). The EPA certification provisions align with provisions that apply to the NHTSA trailer program such that this single certification program meets the requirements of both agencies.

The certification process for trailer manufacturers is very similar in its basic structure to the process for the other Phase 2 vehicle programs, although it has been simplified for trailers. This structure involves pre-certification activities, the certification application and its approval, and end-of-year reporting.

In this section, the agencies first describe the general certification

process and how we developed compliance equations based on the GEM vehicle simulation tool, followed by a discussion of the specified test procedures for measuring the performance of tires and aerodynamic technologies and how manufacturers will apply test results toward compliance and certification. The section closes with discussions of several other certification and compliance provisions as well as provisions to provide manufacturers with compliance flexibility.

(1) General Certification Process

Under the process for certification, manufacturers of all covered trailers are required to apply to EPA for certification.³⁶⁶ In addition, manufacturers of box vans subject to the performance-based standards are required to provide aerodynamic performance test data (see 40 CFR 1037.205) in their applications. EPA expects to provide additional guidance to the regulated industry as the program begins to be implemented, including an overview of the regulations, how to prepare for compliance, and instructions for registering with the EPA. Once a trailer manufacturer is registered with EPA, EPA's Compliance Division in the Office of Transportation and Air Quality will assign a staff certification representative to the company to help them through the compliance process. After this point, manufacturers can arrange to meet with the agencies to discuss compliance plans and obtain any preliminary approvals (e.g., appropriate test methods) before applying for certification.

Trailer manufacturers submit their applications through the EPA "Verify" electronic database, and EPA issues certificates based on the information provided. At the end of the model year, trailer manufacturers submit an end-of-year report to the agencies to complete their annual obligations.

(a) Definition of Model Year

As mentioned previously, consistent with Clean Air Act specifications, EPA's vehicle certification is an annual process. EPA CO₂ emissions standards start to apply for trailers built on or after January 1, 2018, with later standards being introduced by model year. Under the Clean Air Act, the term "model year" refers to a manufacturer's annual production period. Manufacturers may

use the calendar year as the model year, or may choose a different period of production that includes January 1 of that year. Thus, manufacturers have the option to choose any year-long period of production that begins on or before January 1 of the named model year, but no sooner than January 2 of the previous calendar year. For example, at certification, a manufacturer could specify the 2021 model year production period to be July 1, 2020 through June 30, 2021.

(b) Preliminary Considerations for Compliance

Before submitting an application for a certificate, a manufacturer chooses the technologies they plan to offer their customers, and identifies any trailers in their production line that qualify for exclusion from the program.³⁶⁷ Non-box trailers, which are subject to design standards, the manufacturer will need to select which tires and tire pressure systems to include and confirm that their tires meet the LRR performance standards. For box vans subject to performance standards, manufacturers also obtain performance information for these technologies at this time, either from supplier data or their own testing. Manufacturers that choose to perform aerodynamic or tire testing themselves may also need to obtain approval of test methods and perform preliminary testing. Trailer manufacturers relying on data from a third-party aerodynamic device manufacturer would need to verify that these data are approved.

During this time, the manufacturers also decide the strategy they intend to use for compliance by identifying "families" for the trailers they produce. A family is a grouping of similar products that are all subject to the same standard and covered by a single certificate. All products in each trailer subcategory are generally certified as the same family. That is, long box dry vans, short box dry vans, long refrigerated vans, short refrigerated vans, non-box trailers, partial-aero vans (long and short box, dry and refrigerated vans), and non-aero box vans, are each certified as separate trailer families. Manufacturers may combine dissimilar trailers into a single vehicle family to reduce the compliance burden as described in 40 CFR 1037.230(d)(3) and 49 CFR 535.5(e). In general, manufacturers can combine trailers that have less stringent standards with more stringent standards as long as the combined set of trailers

³⁶⁶ As with the other Phase 2 vehicle programs, manufacturers submit their applications to EPA, which then shares them with NHTSA. Obtaining an approved certificate of conformity from EPA is the first step in complying with the NHTSA program.

³⁶⁷ Trailers that meet the qualifications for exclusion do not require a certificate of conformity and manufacturers do not have to submit an application to EPA for these trailers.

meet the more stringent standards. Refrigerated and dry vans of the same length can be combined to meet the dry van standards. Short vans can combine with long vans, meeting the corresponding long van standard. Additionally, non-box trailers can be combined with the non-aero box vans if the manufacturer would like to meet the more stringent non-aero box van design standards with higher-performing tires.

When no averaging is available (*i.e.*, MY 2018 through MY 2026 for full-aero box vans, and all years for remaining trailers), all products within a family need to meet or exceed the standards for that trailer subcategory (except for any trailers included in the manufacturer's allowance for non-complying vehicles (See Section IV.E.(5)(a) below)). This is not to say that, for example, every long box dry van model needs to have identical technologies like skirts, tires, and tire inflation systems, but that every model in that family need to meet the standard for that family.

In MY 2027 and later, full-aero box van manufacturers will still generally have one family per subcategory. However, if a full-aero box van manufacturer subject to performance standards wishes to utilize the averaging provisions, it would need to divide the trailer models in each of the van subcategories/families into subfamilies.³⁶⁸ Each subfamily can be a grouping of box vans that have similar performance levels, even if they use different technologies. We refer to the performance levels for each subfamily as "Family Emission Limits" (FELs). A long box dry van manufacturer could choose, for example, to create two subfamilies in its long box dry van family. Trailers in one of these subfamilies could be allowed to under-comply with the standard (*e.g.*, not apply a tire pressure system) as long as the performance of the other subfamily over-complies with the standard (*e.g.*, installs additional aerodynamic technologies), such that the average of all of the subfamilies' FELs met or exceeded the standard for that family on a production-weighted basis. Section IV.E.(5)(b) below further discusses how the averaging program would function for any such trailer subfamilies.

³⁶⁸ The program essentially requires that manufacturers equip 100 percent of their non-box and special purpose box trailers with tire pressure systems and tires meeting the specified rolling resistance levels. Partial-aero box vans meet a reduced performance standard. As a result, averaging provisions do not apply to these trailer subcategories.

(c) Submitting a Certification Application and Request for a Certificate to EPA

Once the preliminary steps are completed, the manufacturer can prepare and submit applications to EPA for certificate of conformity for each of its trailer families. The contents of the application are specified in 40 CFR 1037.205, though not all items listed in the regulation are applicable to each trailer manufacturer.

For the early years of the program (*i.e.*, MY 2018 through MY 2020), the application must specify whether the trailer manufacturer is opting into the NHTSA voluntary program to ensure the information is transferred between the agencies. Throughout the program, the application must include a description of the emission and fuel consumption reduction technologies that a manufacturer intends to offer. These technologies could include aerodynamic features, LRR tire models, tire pressure systems, or components that qualify for weight reduction. Basic information about labeling, warranty, and recommended maintenance should also be included the application (see Section IV.E.(4) for more information on these additional compliance provisions).

The manufacturer also provides a summary of the plans to comply with the standard. This information includes a description of the trailer family and subfamilies (if applicable) covered by the certificate, the technologies that are used for compliance, and projected sales of its products. For trailers subject to performance-based standards (and not those subject to the design-based standards), in the earlier stages of the program when averaging is not available (or for manufacturers of full-aero vans that do not participate in averaging after MY 2026), additional provisions apply. These manufacturers will include information on the configuration with the worst performance level in terms of CO₂ and fuel consumption offered in the trailer family. Any of these manufacturers that choose to average within their full-aero van families after MY 2026 will include performance information for the projected highest production trailer configuration, as well as the lowest and the highest performing configurations within those families. For all covered trailers, once the certification application is accepted, a certificate is issued and manufacturers can begin selling their trailers.

(d) End-of-Year Obligations

After the end of each year, all manufacturers, including those with design-based standards, need to submit

a report to the agencies presenting production-related data for that year (see 40 CFR 1037.250 and 49 CFR 535.8). In addition, the year's final compliance data (as calculated using the compliance equation) for box van manufacturers subject to performance-based standards will include both CO₂ emissions and fuel consumption information and actual production volumes in order to demonstrate that the trailers met the standards for that year.

In MY 2027 and later, full-aero box van manufacturers that opt to participate in the averaging program will submit a second report that describes their subfamily FELs and a final calculation of their production-weighted average CO₂ and fuel consumption. See 40 CFR 1037.730, 40 CFR 1037.745, and 49 CFR 535.7. All certifying manufacturers need to maintain records of all the data and information that is required to be supplied to EPA and NHTSA for eight years.

(2) Evaluating Trailer Performance for Compliance

The agencies believe that this final compliance program for trailer manufacturers is straightforward, technically robust, transparent, and minimizes administrative burdens on the industry. As described earlier in this section and in Chapter 4 of the RIA, GEM is a customized vehicle simulation model that EPA developed for the Phase 1 program to relate measured aerodynamic and tire performance values, as well as other parameters, to CO₂ and fuel consumption without performing full-vehicle testing. As with the Phase 1 and Phase 2 tractor and vocational vehicle programs, the trailer program uses GEM in evaluating emissions and fuel consumption in developing the trailer standards. However, unlike the tractor and vocational vehicle programs, trailer manufacturers will not use GEM directly to demonstrate compliance with the trailer standards. Instead, we have developed an equation based on GEM that calculates CO₂ and fuel consumption from performance inputs without running the model.

(a) Development of the GEM-Based Trailer Compliance Equation

For compliance with the performance-based standards in the trailer program (*i.e.* the standards for full- and partial-aero long and short box vans), the trailer characteristics that a manufacturer supplies to the equation are aerodynamic improvements (*i.e.*, the change in the aerodynamic drag area,

delta C_dA , from the appropriate bin in m^2), tire rolling resistance (*i.e.*, coefficient of rolling resistance, C_{RR} , in kg/metric ton), the presence of a tire pressure system, and any weight reduction applied in pounds. The use of the equation quantifies the overall performance of the trailer in terms of CO_2 emissions on a grams per ton-mile basis, which can be converted to fuel consumption on a gallons per 1000 ton-mile basis.

Chapter 2.10.5 of the RIA provides a full a description of the development and evaluation of the equation for trailer compliance where the standards are

performance-based. Equation IV–1 is a single linear regression curve that can be used for all box vans in these rules to calculate CO_2 emissions, e_{CO_2} . Unique constant values, C_1 through C_4 , are applied for each of the van types as shown in Table IV–24. Constant C_5 is equal to 0.988 for any trailer that installs an ATIS (accounting for the 1.2 percent reduction given for use of ATIS), 0.990 for any trailer that installs a TPMS, or 1.0 for trailers without tire pressure systems. We found that this equation accurately reproduces the results of GEM for each of the box van subcategories, and the program requires

these trailer manufacturers use Equation IV–1 to calculate CO_2 for compliance. Manufacturers insert their tire rolling resistance level (TRRL), wind-averaged change in drag area (ΔC_dA), weight reduction value (WR) (if applicable), and the appropriate C_5 value if a tire pressure system is installed into the equation and submit the result to EPA. The program provides for manufacturers to use a conversion of 10.180 grams of CO_2 per gallon of diesel to calculate the corresponding fuel consumption values for compliance with NHTSA's regulations. See 40 CFR 1037.515 and 49 CFR 535.6.

$$e_{CO_2} = [C_1 + C_2 \cdot (TRRL) + C_3 \cdot (\Delta C_dA) + C_4 \cdot (WR)] \cdot C_5 \quad (IV-1)$$

TABLE IV–24—CONSTANTS FOR GEM-BASED TRAILER COMPLIANCE EQUATION

Trailer subcategory	C_1	C_2	C_3	C_4	C_5 (tire pressure)		
					None	TPMS	ATIS
Long Dry Van	76.1	1.67	–5.82	–0.00103	1.000	0.990	0.988
Long Refrigerated Van	77.4	1.75	–5.78	–0.00103			
Short Dry Van	117.8	1.78	–9.48	–0.00258			
Short Refrigerated Van	121.1	1.88	–9.36	–0.00264			

These long and short van constants are based on GEM-simulated tractors pulling 53-foot and solo 28-foot trailers, respectively. As a result, aerodynamic testing to obtain a trailer's performance parameters for Equation IV–1 must be performed using consistent trailer sizes (*i.e.*, aerodynamic performance for all lengths of short vans would be tested as a solo 28-foot van, and performance for all lengths of long vans would be tested as a 53-foot van). More information about aerodynamic testing is provided in Section IV.E.(3)(b) below.

The constants for long vans apply for all dry or refrigerated vans longer than 50-feet and the constants for short vans apply for all dry or refrigerated vans 50-feet and shorter. The vans with work-performing devices that may be designated as partial-aero vans would use the same equation constants as their full-aero counterparts for compliance. The partial-aero designation simply allows a van to input different values (*i.e.*, lower delta C_dA) and meet a different standard. Note that compliance with the design-based standards (non-box trailers and non-aero vans) does not require use of the GEM-based equation. Manufacturers supply the TRRL values for their trailer tires and attest that they installed one of the tire pressure systems (TPMS or ATIS) to EPA for compliance.

(b) Use of the Compliance Equation for Box Van Compliance

Box van manufacturers subject to the performance-based standards meet the standards using the GEM-based compliance equation to combine the effects of technologies and quantify the overall performance of the vehicle to demonstrate compliance. Trailer manufacturers obtain delta C_dA and tire rolling resistance values from testing (either from their own testing or from testing performed by another entity as described in Section IV.E.(3)(b)) and attest that they installed a qualifying tire pressure system and/or adopted weight reduction strategies. Manufacturers adopting aerodynamic improvements will compare their measured delta C_dA value to the values shown in Table 2 of 40 CFR 1037.515 (and Table IV–5 previously) and use the appropriate aerodynamic bin value as the aerodynamic input into the equation. The TRRL can be directly applied from measurements. Weight reduction is obtained by summing applicable values in our list of light weight components (Table 3 of 40 CFR 1037.515) or from measurements using the off-cycle provisions. Manufacturers indicate use of TPMS or ATIS with a specified percent reduction in CO_2 and fuel consumption.

Qualifying components for weight reduction can be found in 40 CFR

1037.515(d). Manufacturers that substitute one or more of these components on their box vans sum the weight reductions assigned to each component and enter that total into the equation. As noted in Section IV.D.(1)(d), the equation accounts for weight reduction by assigning one-third of that reduced weight to increase the payload and the remaining weight reduction to reduce the overall weight of the assumed vehicle.

Manufacturers of box vans subject to the performance standards apply the compliance equation separately to each configuration to ensure that all of the trailer configurations they offer need to meet the standard for the given model year. The certification application submitted to EPA includes equation results from the worst performing trailer configuration for each subcategory and the manufacturer attests that no regulated trailer will be sold in a lower performing configuration. If the manufacturer offers a new technology package during the model year, the performance can be evaluated using the equation. If the performance of the new package is lower than the value submitted in the application, the manufacturer would submit a "running change" to EPA to reflect the change. Box van manufacturers will submit a single end-of-year report that will include their production volumes and

confirmation that all of their trailers applied the technology packages outlined in their application.

Any full-aero box van manufacturers that wish to take advantage of the agencies' averaging provision in MY 2027 and later will make greater use of the compliance equation. Before submitting a certificate application, these manufacturers would decide which technologies to make available for their customers and use the equation to determine the range of performance of the packages they planned to offer. The manufacturers would supply these results from the equation in their certificate application and those manufacturers that wish to perform averaging would continue to calculate emissions (and fuel consumption) with the equation throughout the model year and keep records of the results for each trailer package produced. As described in Section IV.E.(1)(d) above, at the end of the year, these manufacturers would submit two reports. One report would include their production volumes for each configuration. The second report would summarize the families and subfamilies, and CO₂ emissions and fuel consumption results from the equation for all of the trailer configurations they build in that model year, including a production-weighted average to show compliance.

For non-box trailers and non-aero box vans, compliance is design-based, not performance-based, and the compliance equation is not needed. As described earlier, the standards for these trailers require the use of tires with rolling resistance levels at or below a threshold, and tire pressure systems (either TPMS or ATIS). Instead of aerodynamic testing data in their certification applications, manufacturers of these trailers submit their tire rolling resistance levels and a description of their tire pressure system(s) to EPA.

(3) Trailer Certification Test Protocols

The Clean Air Act specifies that compliance with emission standards for motor vehicles be demonstrated by the manufacturer using emission test data (see CAA section 206(a) and (b)). As discussed earlier, for the design-based standards (non-box trailers and non-aero vans), the trailer program considers the use of specified LRR tires and tire pressure systems an appropriate surrogate for emission testing, and there are no testing requirements associated with these standards beyond the testing required to show the tires qualify as LRR tires. We expect that tire testing will be performed by the tire manufacturers.

All full- and partial-aero vans covered by the program are subject to performance standards, and compliance is based on measured emission performance. For these trailers, the program uses the GEM-based compliance equation discussed in Section IV.E.(2)(a) above as the official "test procedure" for quantifying CO₂ and fuel consumption performance for trailer compliance and certification (as opposed to use of GEM, which serves this function in the tractor and vocational vehicle programs). Manufacturers input performance information from the applicable trailer technologies into the equation in order to calculate their impact on overall trailer performance. Manufacturers needing aerodynamic and tire rolling resistance performance data obtain it either through their own testing or through a device or tire manufacturer that performed the testing. The program specifies pre-determined values for tire pressure systems and many weight reduction components for manufacturers to apply.

The following subsections describe the approved performance tests for tire rolling resistance and aerodynamic drag in this trailer program. See 40 CFR part 1037, subpart F, for a full description of the performance tests, in particular section 40 CFR 1037.515.

(a) Trailer Tire Performance Testing

Under Phase 1, tractor and vocational chassis manufacturers are required to input the tire rolling resistance level (TRRL) into GEM, and the agencies adopted the provisions in ISO 28580:2009(E)³⁶⁹ to determine the rolling resistance of tires. The tire rolling resistance level (TRRL) is a declared value that is based on a measured value. As described in 40 CFR 1037.520(c), this measured value, expressed as C_{RR}, is required to be the result of measurements of three different tires of a given design, giving a total of at least three data points. Manufacturers specify a C_{RR} value for GEM that is less than or equal to the average of these three results. Tire rolling resistance may be determined by either the vehicle or tire manufacturer. In the latter case, the tire manufacturer provides a signed statement confirming that it conducted testing in accordance with this part.

The Phase 1 tire testing provisions for rolling resistance apply to all of the regulated trailers in the Phase 2 program. In the Phase 2 program, full- and partial-aero box van manufacturers,

subject to the trailer performance-based standards, apply their declared TRRL in the compliance equation. Non-box trailer and non-aero box vans, subject to the design-based standards, simply report the TRRL as part of their certification application. Based on the current practice for Phase 1, we expect the trailer manufacturers to obtain these data from tire manufacturers, but trailer manufacturers have the option to perform tire testing themselves.

The agencies requested comment on adopting a program for tire manufacturers similar to the provision described in Section IV.E.(3)(b)(v) for aerodynamic device manufacturers, through which tire manufacturers would seek preliminary approval of the performance of their trailer tires. 80 FR 40278. CARB supported this option and further requested that EPA create a public database of the tire rolling resistance data submitted to the agency in such preliminary approvals. RMA's comments opposed making tire data available to the public without first developing a rating system for medium and heavy truck tires. The agencies have chosen not to pursue provisions for pre-approved trailer tire rolling resistance data or a public database of this information in this rulemaking, recognizing the overall unresolved issues relating to standard HD truck and trailer testing within the tire industry (as discussed in the Tractor section of this Preamble, Section III.E(1)(e)). Instead, trailer tire manufacturers provide tire rolling resistance values directly to the trailer manufacturers and that information is shared with EPA and NHTSA for certification.

(b) Trailer Aerodynamic Performance Testing

As discussed earlier, manufacturers of trailers subject to performance standards (*i.e.*, most box vans), need to provide EPA with aerodynamic performance data at the time of certification. The purpose of our trailer aerodynamic test procedures is to establish an estimate of the aerodynamic drag experienced by a tractor-trailer vehicle in real-world operation. We based these procedures on the current tractor aerodynamic procedures, including coastdown, wind tunnel, and computational fluid dynamics (CFD) modeling. More specifically, the tests are conducted according to the same test procedures for tractors and trailers, but different provisions apply for the test articles and the data analysis. In the tractor program, the resulting C_{dA} value represents the absolute aerodynamic drag of a tested tractor assumed to be pulling a specified standard trailer. In the trailer program,

³⁶⁹ See http://www.iso.org/iso/iso_catalogue/catalogue_tc/catalogue_detail.htm?csnumber=44770.

the tests measure the difference in C_dA value between the tested trailer as pulled by a standard tractor and a reference trailer pulled by the same standard tractor. In other words, the trailer test procedure is intended to measure the aerodynamic improvements rather than the absolute aerodynamic performance. The agencies chose to base the standards on measurements of aerodynamic improvements in part to reflect the market reality that many trailer manufacturers rely on manufacturers of bolt-on aerodynamic devices for the improvements rather than redesigning their trailer or developing their own components.

To minimize the testing burden, the program specifies that all aerodynamic devices for long box vans (*i.e.*, those greater than 50-feet in length) be evaluated based on 53-foot box vans, and that devices for all trailers 50-feet and shorter be evaluated based on 28-foot box vans. In other words, a manufacturer can use test data from a single trailer to certify all trailers in the same subcategory. As noted previously in Section IV.D.(1) and demonstrated in Chapter 2.10.2.1.2.6 of the RIA, the performance of aerodynamic devices on these two trailer lengths is expected to provide a conservative estimate of the performance on the longer trailers within the same length category. We believe that this compliance approach effectively represents the performance of such devices on the majority of box vans, yet limits the number of such vans that a manufacturer needs to track and evaluate.

The program provides for manufacturers to have flexibility in the devices (or packages of devices) they install on box vans with lengths that differ from 53-feet or 28-feet. In such situations, a manufacturer could use devices that they believe would be more appropriate for the length of the trailer they are producing, consistent with good engineering judgement. For example, they could test skirts on a 28-foot trailer and use longer skirts on 40-foot trailers that they make. No additional testing would be required in order to validate the appropriateness of using the alternate devices on these trailers.

The agencies have structured the final regulations to make wind tunnel testing the primary method for measuring trailer aerodynamic performance. While coastdown testing measures performance of full-scale vehicles, which is generally the agencies' preference for performance testing, wind tunnel testing achieves similar results in terms of delta C_dA , with the added benefit of measuring wind-

averaged values in the same test. In addition, wind tunnel testing is inexpensive relative to other aero test methods and does not require as much time to complete. Thus, it has generally been the preferred method for the trailer industry. Nevertheless, the program provides for manufacturers to use coastdown or CFD methods as described below and fully in 40 CFR 1037.526(b) and 1037.150(x).

The agencies considered making coastdown testing the primary test method for trailers, as it is for the tractor program. However, the delta C_dA approach for the trailer aerodynamic program would require multiple tests to evaluate most configurations. Coastdown testing is a full-scale test method that requires the vehicle, which includes the trailer and an appropriately aerodynamic tractor, be driven on a road or track that meets specified conditions. An important challenge with coastdown testing is that wind and weather restrictions can limit the days in which testing can be performed. Additionally, coastdown testing has higher natural variability due to environmental variability in an uncontrolled system. We have placed an additional restriction on the allowable difference in yaw angles for delta C_dA measurements to reduce this variability (see 40 CFR 1037.526(a)(2)). However, the combination of our test constraints (*e.g.*, restrictions on the wind, temperature, and road conditions), can make it challenging to measure a drag difference from two valid coastdown tests. These factors would make accurate coastdown testing for the trailer program even more time-consuming and expensive relative to the tractor program. Accordingly, we decided that wind tunnel testing is more appropriate for this newly regulated industry.

Coastdown testing has two significant advantages over wind tunnel testing. First, as a full-scale method, it can be directly applied to actual products. Second, full-scale methods may be the only way to reliably test small-scale devices that cannot be appropriately scaled or recreated in wind tunnel or CFD. Although these advantages justify allowing coastdown testing as an alternate method, they do not justify the additional costs that would occur if it were specified as the primary test method for trailers.

In making this determination, the agencies were cognizant of the limited financial ability of trailer manufacturers (and device manufacturers) to absorb testing costs. Unlike the tractor industry, most of the manufacturers in the trailer industry are small- to medium-sized companies. Even the

largest trailer manufacturers are much smaller than the companies that manufacture tractors. Had we established coastdown as the primary method, trailer manufacturers would have needed to not only perform extensive coastdown testing to show equivalency with their preferred methods, but would have also needed to maintain the ability to perform coastdowns on a regular basis like tractor manufacturers are required to under Phase 1 and Phase 2, including owning or maintaining access to an appropriate test tractor or tractors. While this is a manageable burden for the large tractor manufacturers, it would have been a substantial burden for trailer manufacturers, especially the smaller ones. TTMA commented that any of the larger manufacturers in its membership that may do testing would prefer wind tunnel or CFD testing to "contain costs." In conjunction with the NODA, EPA laid out principles related to aerodynamic testing that we intended to follow when applying our compliance oversight to trailers.³⁷⁰ In particular, we indicated that we intended to rely more on our own confirmatory testing, recognizing that both trailer manufacturers and device manufacturers have less financial ability to perform Selective Enforcement Audit (SEA) testing than do tractor manufacturers (see Section IV.E.(4)(f) for more information on SEAs). Under the final regulations, the agencies can perform wind tunnel testing, but would also retain the right to perform coastdown testing, provided we adjusted any coastdown results to account for yaw differences. If we conducted confirmatory testing using coastdowns, we would also need to perform enough runs to minimize variability between the test conditions. Should we measure worse aerodynamic performance (after fully adjusting for methodological differences and accounting for test-to-test variability), we would require the manufacturer to use our test results as the official test results. It is important to emphasize that, because confirmatory testing generally occurs before we have issued a certificate of conformity and before the manufacturer has begun production, there are no penalties or other compliance actions that would result from EPA confirmatory testing. Thus, we do not expect manufacturers using wind tunnels to have any need to

³⁷⁰ "Additional Discussion of Selective Enforcement Audit and Confirmatory Testing for Aerodynamic Parameters for Combination Tractors and for Trailers," February 19, 2015. Docket EPA-HQ-OAR-2014-0827-1625.

separately verify their results using coastdown procedures.

Details of the test procedures can be found in 40 CFR 1037.526 and a discussion of EPA's aerodynamic testing program as it relates to the trailer program is provided in the RIA Chapter 3.2. The following subsections outline the testing requirements for the long term trailer program, as well as simpler testing provisions that apply in the nearer term.

(i) A to B Testing for Trailer Aerodynamic Performance

The agencies expect a majority of the aerodynamic improvements for trailers will be accomplished by adding bolt-on technologies. As just explained above, a key difference between the tractor program and the trailer program is that while the tractor test procedures provide a direct measurement of an absolute C_dA value for each tractor model, aerodynamic improvements for trailers are evaluated by measuring a change in C_dA (delta C_dA) relative to a baseline without aerodynamic improvements. Specifically, trailer tests are performed as "A to B" tests, comparing the aerodynamic performance of a tractor-trailer without a trailer aerodynamic device (or package of devices) to one with the device (or package) installed. As noted below, this approach can be applied if changes are made to the aerodynamic design of a trailer as well. See RIA Chapter 2.10.2.1.2 for more justification for this A to B approach.

In essence, an A to B test is a pair of tests: one test of a baseline tractor-trailer in a "no-control" configuration with zero trailer aerodynamic improvements (A), and one test that includes the aerodynamic improvements to be tested (B). However, because an A test relates to a B test only with respect to the test method and the basic tractor-trailer vehicle, one A test could be used for many different B test configurations. This type of testing results in a delta C_dA value instead of an absolute C_dA value. For the trailer program, the vehicle configuration in the A test includes a standard tractor that meets specified characteristics (40 CFR 1037.501(h)), and a baseline trailer with no aerodynamic improvements. The entity conducting the testing (*e.g.*, the trailer manufacturer, a contractor, or an aerodynamic device manufacturer, as discussed below) performs the test for this configuration according to the procedures in 40 CFR 1037.526 and repeats the test for the B configuration, which includes the trailer aerodynamic package/device(s) being tested. The delta C_dA value for that trailer with that

aerodynamic improvement is the difference between the C_dA values obtained in the A and B tests.

The agencies note that it was relatively straightforward in Phase 1 to establish a standard trailer with enough specificity to ensure consistent testing of tractors, since there are relatively small differences in aerodynamic performance of base-model dry box vans. However, as discussed in Chapter 2.10 of the RIA, small differences in tractor design can have a significant impact on overall tractor-trailer aerodynamic performance. An advantage of an A to B test approach for trailers is that many of the effects due to differences in tractor design are minimized, which allows different models of tractors to be used as standard tractors in testing without compromising the evaluation of the trailer aerodynamic technology. Thus, the relative approach does not require the agencies to precisely specify a standard tractor, nor does it require trailer manufacturers to purchase, modify or retain a specific tractor model in order to evaluate their trailers.

In the event that a trailer manufacturer makes major changes to the aerodynamic design of its trailer in lieu of installing add-on devices, it could use the same baseline trailer for the A configuration as could be used for bolt-on features. In both cases, the baseline trailer would be a manufacturer's standard box van. Thus, the manufacturer of a redesigned trailer would get full credit for any aerodynamic improvements it made.

As discussed in Chapter 2.10 of the RIA, measured drag coefficients and drag areas can vary slightly depending on the test method used. In general, absolute wind-averaged C_dA values measured using wind tunnels and CFD tend to be higher than values measured using the near-zero yaw coastdown method. The Phase 1 and Phase 2 tractor program use coastdown testing as the reference test method, and the agencies require tractor manufacturers to perform at least one test using that method to establish a correction factor to apply to each of the alternative test methods. The proposed trailer regulations referred to coastdown as our reference method, although we noted that the size of the bins and the use of delta C_dA (as opposed to absolute values) minimized the significance of variability between test methods. 80 FR 40280. CARB recommended that we require a reference method in our aerodynamic testing, but provided no data to support their recommendation.

As noted already, the agencies have established the wind tunnel method as

the primary method. Like the tractor program, the allowance to use alternate aerodynamic test procedures provides for adjustments to make the measurements equivalent to the primary method. This is done to ensure that the manufacturer is neither advantaged nor disadvantaged by using the alternate method, relative to results they would have obtained using the primary method. However, because determining equivalency between methods can be burdensome, the agencies are adopting in 40 CFR 1037.150(x) an interim allowance to use certain specific approximations based on data currently available to us. Manufacturers would not be required to justify using these approximations or to seek prior approval for them. Nevertheless, in the unlikely event that we determine that these approximations overstate actual aerodynamic performance for a particular trailer or device, we would not allow the manufacturer to use the approximated values for certification and they would be required to use other more reasonable adjustments.

Our test results shown in Chapter 2.10 of the RIA, show that wind tunnel and CFD produce wind-averaged delta C_dA values within the same bin for the devices tested. Thus, this interim provision allows CFD results to be used without adjustment. Coastdown delta C_dA results, which are not wind-averaged, may be in the same bin, but we note that the tails showed more yaw dependence and coastdown tests under-predicted the performance of tails relative to wind-averaged methods. We anticipate some additional current and future devices may be sensitive to yaw angle, and our interim provision accounts for this. Manufacturers that choose to use coastdown testing can use their results without adjustment, or, if they suspect their device is affected by yaw angle, they can use other testing or analytical methods to demonstrate a means of adjusting their near-zero yaw results to a wind-averaged equivalent 4.5-degree value. The bin values in Section IV.E.(3)(b)(iv), which were updated based on additional aerodynamic test data collected between the NPRM and final rules, are based on our wind tunnel testing results, though our results suggest that most CFD and coastdown results will fit into the same bins. See RIA Chapter 2.10.2.1.3.

(ii) Standard Tractor for Aerodynamic Testing in the Trailer Program

The agencies are adopting a set of characteristics that qualify a tractor to be used in trailer aerodynamic compliance testing. EPA's trailer testing program investigated the impact of

tractor aerodynamics on the performance of trailer aerodynamic technologies, as mentioned in Chapter 2.10.2.1.2.2 of the RIA. We found the A to B test strategy reduces the degree of precision with which the standard tractor needs to be specified. Instead of identifying a specific make and model of a tractor to be used over the entire duration of the program, the agencies identified an appropriate aerodynamic performance threshold that maintains a relatively consistent level of performance between trailers. Tractors used in trailer aerodynamic tests must meet Phase 2 aerodynamic Bin III or better tractor requirements. We believe the majority of tractors in the U.S. trucking fleet will be Bin III or better in the timeframe of this rulemaking, and trailer manufacturers have the option to choose higher-performing tractors in later years as tractor technology improves. See Section III.D.2.c.i. The standard tractor for long-box vans is a Class 8 high-roof sleeper cab. The standard tractor for short box vans is a Class 7 or 8 high roof day cab with a single drive axle (*i.e.*, 4x2 axle configuration). Trailer or device manufacturers are free to choose any standard tractor that meets these criteria in their aerodynamic performance testing. See 40 CFR 1037.501.

The compliance equation used to determine compliance with the trailer standards is based on GEM, so our discussion of the feasibility of our standards (Section IV.D.(2)) includes a description of the tractor-trailer vehicle used in GEM. The agencies proposed to require use of a 6x4 Class 8 sleeper cab for long box van aerodynamic testing, and a 6x4 Class 8 day cab for short box van testing. 80 FR 40279. We believe Class 8 tractors are more widely available, which will make it easier for the trailer industry to obtain a qualified tractor if they choose to perform trailer testing. In order to align with the test procedures, we also proposed to consistently model a Class 8 tractor across all trailer subcategories in GEM. CARB supported the use of Class 8 tractors in their comments. However, EPA encountered difficulty in meeting the test procedure-specified tractor-trailer gap width when using a dual drive axle day cab in one of our short box van wind tunnel tests due to the location of the landing gear relative to the kingpin. As a result, we are changing the standard tractor specifications for aerodynamic testing to require the use of a 4x2 tractor for short trailers. While we expect most manufacturers will use tractor-trailer models in wind tunnel or CFD testing,

we recognize that there are fewer 4x2 tractors available for full-scale testing, and we are adopting provisions that testers can use either a Class 8 or Class 7 day cab tractor to address availability concerns. We believe the external aerodynamic characteristics of Class 7 and Class 8 day cabs are very similar and the engine performance differences between the two tractor classes would not impact the aerodynamic performance in terms of delta C_dA . Note that a Class 7 4x2 day cab tractor is used for all short van default tractor-trailer vehicles within GEM and represented in the GEM-based equation (see Table IV–8).

Daimler requested that we choose a *single* tractor for all trailer testing to ensure consistency over time. As stated above, the agencies agree that the tractor does have the potential to influence the aerodynamic performance of trailers. As discussed above, however, we believe that influence is reduced with use of a delta C_dA . Additionally, we believe it would be a significant burden on the trailer industry to require manufacturers and suppliers to acquire a specific tractor make and model over the timeframe of the rules. Thus, the final trailer program does not require the use of a specific tractor make for the Phase 2 trailer program.

(iii) Accounting for Wind Impacts When Measuring Aerodynamic Performance

The agencies proposed to determine the delta C_dA for trailer aerodynamic performance using the zero-yaw (or head-on wind) values from any of the approved test procedures. However, based on comments received, we are revising the final program to be based on wind-averaged results, similar to the tractor program. The agencies recognize the value of wind-averaging to better reflect the performance expected in real-world operation, but at the time of proposal, we believed the use of a zero-yaw delta C_dA would reduce the number of tests compared to generating a wind-averaged value from a sweep of yaw angles. Additionally, it is relatively straightforward to generate wind-averaged C_dA values from wind tunnel and CFD, but there is a significant increase in test burden to obtain wind-averaged results from coastdown tests. Our intent was to ensure parity between test procedures, such that manufacturers would have the several options to test aerodynamic performance.

The agencies received comment on this issue, in the context of the proposed tractor standards, suggesting that the C_dA measured at a yaw angle of 4.5 degrees is very similar to the wind-averaged C_dA calculated at 7 degrees/65

MPH. The agencies evaluated our own test data using an average of +4.5 degrees and –4.5 degrees to minimize the effect of potential facility asymmetry, and found that the results were within two percent of the corresponding wind-averaged values (See Section III.E.2.a and Chapter 3.2 of the RIA). Adoption of this surrogate angle approach reduces the cost of generating a wind-averaged value from wind tunnel and CFD procedures.³⁷¹ Consequently, the tractor program uses an average C_dA measured at +4.5 and –4.5 degree yaw angles as a surrogate wind-averaged value (see RIA Chapter 3.2 for more information). However, it does not address the increased burden for conducting coastdown tests.

The agencies received comment from TTMA that “repetitive” coastdown testing would rarely be used by its trailer manufacturer members. Instead, manufacturers that do choose to perform their own testing will likely rely on CFD and wind tunnel tests. Because we are establishing the wind tunnel method as the primary method, and because we expect it to also be the most commonly used method, we no longer have test burden concerns about requiring wind-averaging. Therefore, the agencies believe we can adopt aerodynamic test procedures for trailers that require wind-averaged delta C_dA values, as represented by an average of results from +4.5 and –4.5 degree yaw angles, for compliance. We believe that coastdown testing will be chosen by a small number of manufacturers and the burden of performing this optional test on the overall industry will be relatively small. EPA may rely on coastdown testing in its own confirmatory testing, and the agency will accept the additional burden of correcting to a wind-averaged value.

(iv) Bins for Aerodynamic Performance

As mentioned in Section IV.D., the trailer program uses aerodynamic bins to account for testing variability and to provide consistency in the performance values used for compliance. We developed these bins in terms of delta C_dA ranges, and we designed them to be broad enough to cover the range of uncertainty seen in our aerodynamic testing program in terms of test-to-test variability as well as variability due to

³⁷¹ CFD test contracts are often priced for individual yaw angles. Wind tunnel test contracts are often priced for an entire yaw sweep. Limiting our measurement requirement to one or two yaw angles is expected to reduce the cost of generating a wind-averaged value from CFD, but will only reduce the cost from wind tunnel tests if the manufacturer chooses to do individual yaw angles in lieu of the customary sweep.

differences in test method, tractor models, trailer models and device models. The bins are somewhat different than in the proposal, as discussed in Section IV.D.(1)(a)(ii) above RIA Chapter 2.10.2.1.3.

TABLE IV–25—AERODYNAMIC BINS USED TO DETERMINE INPUTS FOR TRAILER CERTIFICATION

Delta C _d A measured in testing	Bin	Delta C _d A input for compliance
<0.1	Bin I	0.0
0.10–0.39	Bin II	0.1
0.40–0.69	Bin III	0.4
0.70–0.99	Bin IV	0.7
1.00–1.39	Bin V	1.0
1.40–1.79	Bin VI	1.4
≥1.8	Bin VII	1.8

A manufacturer that wishes to perform testing first identifies a standard tractor according to 40 CFR 1037.501(h) and a representative baseline trailer with no aerodynamic features (or models of these vehicles), then performs the A to B tests with and without aerodynamic improvements to obtain a delta C_dA value. The manufacturer uses Table IV–25 to determine the appropriate bin based on their measured delta C_dA. Each bin has a corresponding delta C_dA threshold value that is the value manufacturers insert into the compliance equation.

(v) Aerodynamic Device Testing Compliance Path

The agencies recognize that much of the trailer manufacturing industry may have little experience with aerodynamic performance testing. For this reason, the program includes a compliance option that we believe minimizes the testing burden for trailer manufacturers, and at the same time meets the requirements of the Clean Air Act and of EISA by providing reasonable assurance that the anticipated CO₂ and fuel consumption benefits of the program will be realized in real-world operation. This approach provides an opportunity for trailer manufacturers to choose technologies with pre-approved test data for installation on their new trailers without performing their own aerodynamic testing. We note that this testing option is consistent with recommendations of the Small Business Advocacy Review (SBAR) Panel, which is summarized in Section XIV.D and Chapter 12 of the RIA.

The trailer program provides for trailer aerodynamic device manufacturers to seek preliminary approval of the performance of their devices (or combinations of devices)

based on the same performance tests described previously. Trailer manufacturers could then choose to use these devices and apply the approved performance levels in the certification application for their trailer families. A device manufacturer would need to perform the required A to B testing using a tractor-trailer that meets the requirements specified in 40 CFR 1037.211 and 1037.526 and submit the performance results, in terms of delta C_dA, directly to EPA.³⁷² EPA would require much of the same information from the device manufacturers as it would normally require during certification, including the technology name, a description of its proper installation procedure, and its corresponding delta C_dA derived from the approved test procedures. See 40 CFR 1037.211.

Once a device manufacturer has obtained this preliminary approval, it could supply the same information to any trailer manufacturers that wish to install its devices. When the trailer manufacturer certifies, the agencies would merely verify that the values in the trailer manufacturer's certification application are those already approved for the device manufacturer. To ease the transition for MYs 2018 through 2020, we proposed and are adopting a flexibility to allow pre-approval of certain data accepted by the EPA SmartWay aerodynamic verification program. Section IV.E.(5)(c) below describes how a device manufacturer can use certain test data generated for SmartWay verification as a part of its pre-approval in the early years of the program.

The program also allows trailer manufacturers to use multiple devices with individually pre-approved test data on a single trailer configuration, provided each device does not impair the effectiveness of the other(s), consistent with good engineering judgment.³⁷³ 40 CFR 1037.211 outlines a process for combining the effects of multiple devices to determine an appropriate delta C_dA value for compliance. More specifically, manufacturers would fully count the technology with largest delta C_dA value,

discount the second by 10 percent, and discount each of the remaining additional technologies by 20 percent. This discounting acknowledges the complex interactions that can occur among individual aerodynamic devices and provides a conservative value for the impact of the combined devices (see the analysis of device combinations in RIA Chapter 2.10). For example, a manufacturer applying three separately tested devices with delta C_dA values of 0.40, 0.30, and 0.10 would calculate the combined delta C_dA as:

$$\text{Delta C}_{dA} = 0.40 + 0.90 \cdot 0.30 + 0.80 \cdot 0.10 = 0.75 \text{ m}^2$$

The agencies believe that discounting the delta C_dA values of individually-tested devices used as a combination provides a modest incentive for trailer or device manufacturers to test and get EPA pre-approval of the combination as an aerodynamic system for compliance. To avoid this discounting, device manufacturers can test a trailer incorporating a combination of devices and receive EPA pre-approval for data from that combination. Trailer manufacturers could then use the test results from that specific combination for certification.

Note that the aerodynamic bins of Table IV–25 do not apply to aerodynamic data that device manufacturers submit to EPA for pre-approval. The pre-approved data will have greater precision than the bin-averaged values shown in Table IV–25. Therefore, trailer manufacturers calculating a delta C_dA value based on combinations of pre-approved data use the exact numbers submitted by the device manufacturers to calculate the discounted delta C_dA, and thus select an appropriate bin value for compliance based on that result. The process to obtain approval is outlined in 40 CFR 1037.211.

The agencies note that many of the largest van manufacturers are already performing aerodynamic test procedures to some extent, and the agencies expect other van manufacturers will increasingly be capable of and interested in performing these tests as the program progresses. The device testing approach is intended to allow trailer manufacturers to focus on and become familiar with the certification process in the early years of the program and, if they wish, begin to perform testing in the later years, when it may be more appropriate for their individual companies. This approach does not preclude trailer manufacturers from performing their own testing at any time, even if the technologies they wish to install are already pre-approved. For

³⁷² Note that in the event a device manufacturer submits false or inaccurate data to EPA, it could incur liability for causing a regulated entity to commit a prohibited act. See 40 CFR 1068.101(c). This same potential liability exists with respect to information provided by a device manufacturer directly to a trailer manufacturer.

³⁷³ A trailer manufacturer needs to use good engineering judgement (as defined in 40 CFR 1068.5) in combining devices for compliance in order to avoid combinations that are not intended to work together (e.g., both a side skirt and an under-body device).

example, a manufacturer that believed a specific trailer actually performed in a more synergistic manner with a given device than the device's pre-approved delta C_dA value suggested could perform its own testing and submit the results to EPA for certification.

STEMCO, an aerodynamic device manufacturer, commented in support of the proposed pre-approval option, but also supported the agencies publishing information about the testing performed by device manufacturers for their devices to be pre-approved. The agencies are not committing to publish the pre-approved aerodynamic data at this time. We do note that once data are submitted to EPA and the device is introduced into commerce, the data are available to the public at their request and the information gathered may be published by outside stakeholders.

(4) Additional Certification and Compliance Provisions

(a) Trailer Useful Life

Section 202(a)(1) of the CAA specifies that EPA is to propose emission standards that are applicable for the "useful life" of the vehicle. NHTSA is adopting EPA's proposed useful life requirements for trailers, to ensure that manufacturers consider in their design process the need for fuel efficiency standards to apply for the same duration as the EPA standards. Based on our own research and discussions with trailer manufacturers, EPA and NHTSA are adopting a regulatory useful life value for trailers of 10 years, as proposed. This useful life value represents the average duration of the initial use of trailers, before they are moved into less rigorous duty (e.g., limited use or storage). We note that the useful life value is 10 years or a mileage threshold for other heavy-duty vehicles. However, unlike for the other vehicles, the program does not include a parallel mileage value for trailers. This would require odometers on trailers, and we do not believe that mandating odometers would be appropriate for this purpose.

With this useful life provision, trailer manufacturers are responsible for designing and building their trailers so that they will be able to meet the CO₂ emissions and fuel consumption standards for 10 years after the trailer is produced, provided that they are properly maintained. For technologies at issue here, we believe that this requirement is essentially the same as customers' existing durability expectations. The useful life requirements do not include liability for damage to or removal of devices by users. Instead, trailer manufacturers

must ensure at the time of sale that devices are properly installed and able to maintain functionality throughout the useful life. We believe that manufacturers will be able to demonstrate at certification that their trailers, including all bolt-on technologies used as emissions controls, will comply with the CO₂ and fuel consumption standards for the useful life of the trailers without separate durability testing. The aerodynamic technologies that we expect manufacturers to use to comply with the trailer standards, including side skirts and boat tails, are designed to continue to provide their full potential benefit indefinitely as long as no serious damage occurs.

Regarding a useful life value for trailer tires, we recognize that the original lower rolling resistance tires will wear over time and will be replaced several times during the useful life of a trailer, either with new or retreaded tires. As with the Phase 1 tractor program, to help ensure that trailer owners have sufficient knowledge of which replacement tires to purchase in order to retain the as-certified emission and fuel consumption performance of their trailer for its useful life, the trailer program requires that trailer manufacturers supply adequate information in the owners manual to allow the trailer owner to purchase replacement tires meeting or exceeding the rolling resistance performance of the original equipment tires. (Note that the "owners manual" need not be a physical document, but could be made available on line). We believe that the favorable fuel consumption benefit of continued use of LRR tires generally results in proper replacements throughout the 10-year useful life. Finally, the program requires that tire pressure systems remain effective for at least the 10-year useful life, although some servicing may be necessary by the customer. See also the related discussions below in Section IV.E.(4)(c) (Emission-Related Warranty) and Section IV.E.(4)(d) (Maintenance).

(b) Emission Control Labels

Historically, EPA-certified vehicles are required to have a permanent emission control label affixed to the vehicle. The label facilitates identification of the vehicle as a certified vehicle. For the trailer program, EPA requires that the labels include the same basic information as we require for tractor labels in Phase 1. For trailers, this information includes the manufacturer, a trailer identifier such as the Vehicle Identification Number, the trailer family and

regulatory subcategory, the date of manufacture, and compliance statements. Although the Phase 2 label for tractors does not include emission control system identifiers (as previously required for tractors in the Phase 1 program in 40 CFR 1037.135(c)(6)), the trailer program requires that these identifiers be included in the trailer labels. See 40 CFR 1037.135 for a list of general requirements for emissions labels, which includes a reference to Appendix III for appropriate abbreviations for trailer technologies.

(c) Emission-Related Warranty

Section 207 (a) of the CAA requires manufacturers to warrant their products to be free from defects that could otherwise cause non-compliance with emission standards. For purposes of the trailer program, EPA requires trailer manufacturers to warrant all components that form the basis of the certification to the CO₂ emission standards. The emission-related warranty covers all aerodynamic devices, lower rolling resistance tires, tire pressure systems, and other components that may be included in the certification application. Note that the emission-related warranty is completely separate from any other warranties a manufacturer might offer.

The trailer manufacturer needs to warrant that these emission-related components and systems are designed to remain functional for the warranty period. We note that this emission-related warranty, and the trailer manufacturer's financial responsibility for repairs, does not apply to components that are damaged in collisions or through abuse; nor does it cover components that experience wear with normal use. This warranty is meant to apply to defects in the product or improper installation by the manufacturer. Based on the historical practice of requiring emissions warranties to apply for half of the useful life, we are adopting a warranty period for trailers of five years for everything except tires. For trailer tires, we apply a warranty period of one year.

Utility and Great Dane noted in their comments that the warranty of current ATIS that they are aware of is limited to three years. However, we view this as a business decision by the ATIS manufacturers, rather than as a reflection of the actual durability of the systems. With proper maintenance, we are aware of no reason that these systems would be unable to meet the durability requirements of the trailer program or to be designed to last the full useful life of the trailer if properly maintained. See the Maintenance

discussion at IV.E.(4)(d) below. We believe a five year emission-related warranty is justified, but we note that trailer manufacturers can specify that their warranty depends on the proper maintenance of components. Manufacturers can offer a more generous warranty if they choose; however, the emission-related warranty may not be shorter than any other warranty they offer without charge for the trailer. NHTSA is not adopting any warranty requirements relating to its trailer fuel consumption program.

At the time of certification, manufacturers need to supply a copy of the warranty statement that they supply to the end customer. This document outlines what is covered under the GHG emissions related warranty as well as the duration of coverage. Customers also need to have clear access to the terms of the warranty, the repair network, and the process for obtaining warranty service.

(d) Maintenance

In general, EPA requires that vehicle manufacturers specify schedules for any maintenance needed to keep their product in compliance with emission standards throughout the useful life of the vehicle (CAA section 207(a)). For trailers, such maintenance could include adjustments to fairings or service to tire pressure systems. EPA believes that any such maintenance is likely to be performed by operators to maintain the fuel savings of the components. If manufacturers believe that the durability of their trailer's performance is contingent on proper maintenance of these systems, they must include a corresponding maintenance schedule in their certification applications.

Since lower rolling resistance tires are key emission control components under this program, and they will likely require replacement at multiple points within the life of a vehicle, it is important to clarify how tires fit into the emission-related maintenance requirements. Although the agencies encourage the exclusive use of LRR tires throughout the life of trailers vehicles, we do not hold trailer manufacturers responsible for the actions of end users. We do not see this as problematic because, as noted above, we believe that trailer end users have a genuine financial motivation for ensuring their vehicles are as fuel efficient as possible, which includes purchasing LRR replacement tires and that they will continue to use them once they are accustomed to their use. Therefore, as mentioned in Section IV.E.(4) above, to help ensure that trailer owners have

sufficient knowledge of which replacement tires to purchase in order to retain the as-certified emission and fuel consumption performance of their trailer, the program requires that trailer manufacturers supply adequate information in the owners manual to allow the trailer owner to purchase tires meeting or exceeding the rolling resistance performance of the original equipment tires. (As discussed above, note that the "owners manual" need not be a physical document, but could be made available on line). Manufacturers submit these instructions to EPA as part of the application for certification.

(e) Post-Useful Life Modifications

The Clean Air Act generally prohibits any person from removing or rendering inoperative any emission control device installed for compliance, such as those needed to comply with the requirements of 40 CFR part 1037. However, in 40 CFR 1037.655 EPA clarifies that certain vehicle modifications are allowed after a vehicle reaches the end of its regulatory useful life. This section applies to trailers, since it applies to all vehicles subject to 40 CFR part 1037.

The provisions of 40 CFR 1037.655 clarify that owners may modify a vehicle for the purpose of reducing emissions, provided they have a reasonable technical basis for knowing that such modification will not increase emissions of any other pollutant, but emphasizes that EPA presumes such modifications to be more appropriate for second owners. In the case of trailers, an owner would need to have information that would lead an engineer or other person familiar with trailer design and function to reasonably believe that the modifications will not increase emissions of any regulated pollutant. In the absence of such information, modifications during or after the trailer's useful life would constitute tampering with an emission control system. Thus, this provision does not provide a blanket allowance for modifications after the useful life.

This section does not specifically apply with respect to modifications that occur within the useful life period, other than to note that many such modifications to the vehicle during the useful life are presumed to violate CAA section 203(a)(3)(A). EPA notes, however, that this is merely a presumption, and would not prohibit modifications during the useful life where the owner clearly has a reasonable technical basis for knowing the modifications will not cause the vehicle to exceed any applicable standard.

(f) Confirmatory Testing and Selective Enforcement Audits (SEA) for GEM Inputs

In Phase 2, vehicle performance for box vans (except non-aero box vans) is measured using a GEM-based equation, which accepts input parameters related to aerodynamics, tire rolling resistance, and trailer weight. Trailer manufacturers are responsible for obtaining performance measures for these parameters through valid testing according to the specified test procedures. The Clean Air Act authorizes EPA to perform its own testing to confirm the manufacturer's data. This testing, which is called confirmatory testing, is conducted prior to issuing a certificate. The Act also authorizes EPA to require manufacturers to conduct Selective Enforcement Audits (SEA), which would involve testing performed on production vehicles before they enter into commerce.

The agencies are finalizing a list of lightweight trailer components that can be installed by trailer manufacturers and used in certification. Additionally, we are assigning a set percent reduction value to qualifying tire pressure systems (*i.e.*, ATIS and TPMS) that manufacturers can apply if they install these systems. Thus, because these are agency-default values rather than the manufacturers' measured or declared values, we will not hold trailer manufacturers responsible for the accuracy of these values. Additionally, we expect most trailer manufacturers will obtain LRR tire information directly from the tire manufacturers and many trailer manufacturers will install aerodynamic devices with data that was pre-approved by EPA. Information provided by a third party (such as a tire or device manufacturer) to a regulated entity for compliance is treated as though it was submitted directly to EPA. EPA has the authority to verify such data and hold the third party responsible for any falsified data, since submission of such data could incur liability for causing a regulated entity to commit a prohibited act. See 40 CFR 1068.101(c).

Of all of the performance measures for trailers, we believe aerodynamic testing has the greatest potential for variability and these results are likely to receive the most scrutiny. In the NPRM, we proposed to generally apply the same SEA and confirmatory testing structures to tractors and trailer with respect to aerodynamics. However, we also proposed to retain the authority to require *component* manufacturers to perform SEAs where certification relies

on their test data. See, *e.g.* section 1037.301(d)(4) of the proposed regulations.

We are revising the SEA and confirmatory testing structures for trailers based on further consideration and comments received from the trailer manufacturing industry (TTMA). In general, the final regulations reflect the following principles:

- Due to the smaller number of possible trailer configurations (compared to tractor configurations), it would be more possible for EPA to rely on confirmatory testing for trailer aerodynamics.
- Since test-to-test variability for individual coastdown runs can be high, confirmatory test determinations should be based on average values from multiple runs.
- Trailer manufacturers and trailer component manufacturers have less financial ability to perform SEAs than do tractor manufacturers. Nevertheless, EPA should retain the authority to require trailer and trailer component manufacturers to perform SEAs, especially where EPA has reason to believe the trailers are non-compliant.
- Given the limited ability to eliminate uncertainty, compliance determinations should consider the statistical confidence that a true value lies outside a bin.

EPA will generally try to duplicate a manufacturer's test setup in any confirmatory testing (which would include the standard tractor) unless we have reason to believe an inappropriate setup was used. While our test results presented in Chapter 2.10 of the RIA show that the trailer program's delta C_dA approach reduces the tractor's impact on trailer results, to the extent practical, EPA will use the same standard tractors that manufacturers used in their testing.

We believe that, although the final compliance structure for trailers is simpler than for tractors, it will still provide a strong incentive for manufacturers to act in good faith. In particular, the regulations emphasize the final value of EPA's auditing records and inspecting production components, rather than requiring manufacturers to perform expensive testing. Thus, EPA expects to require manufacturers to perform SEA testing only when we have reasonable evidence leading us to believe a manufacturer have not provided accurate test data. See Section III.E.(2)(a)(ix) for a discussion of how EPA would conduct an aerodynamic SEA.

(g) Importation of New Trailers

Manufacturers have raised concerns about enforcement of emission standards for new trailers that are imported into the United States. This poses unique challenges at the point of entry, because new trailers may be carrying cargo and are therefore nearly indistinguishable from trailers that have already been imported or otherwise placed into service. We are not adopting any new or different compliance provisions in this rulemaking to address this; however, we intend to work cooperatively with Customs and Border Protection and other agencies to ensure that first-time state registration of new trailers includes verification that the trailer manufacturers have certified them to meet U.S. emission and fuel consumption standards. We expect this to be similar to the current system for ensuring that new, imported trailers meet NHTSA safety standards.

A related concern applies for foreign-based trailers traveling in the United States for importing or exporting cargo. Such trailers are not subject to emission and fuel consumption standards unless they are considered imported into the United States. U.S. cabotage law prohibits foreign truck drivers from carrying product from one point to another within the United States. Effective enforcement of this cabotage law will help prevent manufacturers of noncompliant foreign-produced trailers from gaining a competitive advantage over manufacturers of compliant domestic trailers.

(5) Flexibilities

The trailer program that the agencies are adopting incorporates a number of provisions that have the effect of providing flexibility and easing the compliance burden on trailer manufacturers while maintaining the expected CO₂ and fuel consumption benefits of the program. Among these is the basic approach we used in setting the trailer standards, including the staged phase-in of the standards, which gradually increase the CO₂ and fuel consumption reductions that manufacturers need to achieve over time as they also increase their experience with the program. As described in Section IV.E.(3)(b)(v), another of these is the process for device manufacturers to submit test data directly to EPA for review by the agencies in advance of formal certification, allowing a trailer manufacturer to reduce the amount of testing needed to demonstrate compliance or avoid it altogether.

In addition to these provisions inherent to the trailer program, this

section describes additional options the agencies are adopting that we believe will be valuable to many trailer manufacturers.

(a) Limited Allowance of Non-Complying Trailers

As described in Section IV.B. above the agencies are not finalizing the proposed provisions that would have allowed manufacturers to comply with the trailer standards using averaging before MY 2027. As a result, in the absence of mitigating provisions, manufacturers would need to comply with the applicable standards for all of their trailers. The agencies received comment, primarily from trailer manufacturers, that, without the flexibility of averaging, trailer manufacturers should be allowed to "carve-out" a set percentage of their sales that would not be required to meet the standards. Stoughton Trailers suggested a 20 percent carve-out.

The agencies considered this concept and this final program provides each manufacturer with a limited "allowance" of trailers that do not need to meet the standards. In determining an appropriate value for this allowance, the agencies sought to balance the need for some degree of flexibility in the absence of averaging while minimizing changes in the competitive relationships among larger and smaller trailer manufacturers. An allowance of 20 percent, as suggested by Stoughton, is problematic, since the annual production for individual trailer manufacturers varies so widely. An allowance of 20 percent for a very large manufacturer could very well represent the same volume of trailers as an entire year's sales for a small manufacturer. This in turn could result in a situation where a large number of non-complying trailers would be on the market, potentially attracting customers away from smaller manufacturers that needed to market complying trailers.

Because of this, the agencies estimated a representative volume of trailers based on the 2015 Trailer Production Figures published by Trailer-BodyBuilders.com.³⁷⁴ The smallest box van manufacturer in the list produced 1800 dry freight vans in 2015. Twenty percent of that production is 360 trailers. The agencies are adopting an interim provision providing box van manufacturers an allowance of 20 percent of their production (up to a maximum of 350 units) that are not

³⁷⁴ 2015 Trailer Production Figures Table, Schenk, Paul, March 4, 2016. Accessed January 4, 2016. Available at: <http://trailer-bodybuilders.com/trailer-output/2015-trailer-production-figures-table>.

required to meet the standards for model years 2018 through 2026 when we do not include averaging. All lengths of box vans, including both dry and refrigerated, produced by a given manufacturer count toward the allowance.

While averaging does not apply for partial- and non-aero box trailers at any point in the program, the agencies believe manufacturers can also benefit from the ability to exempt some trailers from these subcategories in the early years as they transition into the full program. For MY 2018 through 2026, manufacturers can include partial- and non-aero box trailers in their 350 box van allowance. In MY 2027, we believe all partial- and non-aero box vans can meet the reduced standards for their given subcategories.

Non-box trailers have design-based tire standards and averaging thus does not apply for this subcategory. Similar to the partial- and non-aero box vans, we also believe non-box manufacturers can benefit from a transitional exemption allowance. The agencies are adopting a separate allowance for non-box trailers, because their production volumes differ and many non-box trailer manufacturers do not build box vans. Using the same trailer production figures, we found that the smallest non-box trailer manufacturer in the list produced 1325 trailers in 2015 and twenty percent of that production is 265 trailers. From MY 2018 through 2026, non-box trailer manufacturers can exempt 20 percent or 250 trailers from the applicable tire standards. By MY 2027, we believe all non-box trailers can incorporate the tire technologies required by the design standards.

The agencies estimate that the box van and non-box trailer allowances translate on average to less than two percent of production across the trailer industry, and the agencies believe that this minor degree of loss of emission and fuel consumption reduction benefits is more than offset by the flexibility which, as pointed out earlier, may be needed by this newly regulated industry segment. These allowances are specified in 40 CFR 1037.150 and 49 CFR 535.3.

(b) Averaging Provisions for the Late Years of the Trailer Program

The agencies proposed to allow trailer manufacturers to use averaging throughout the phase-in of the program as one option for complying with the trailer standards. As noted, we received nearly unanimous comments, in response to the pre-proposal SBREFA panel and to the NPRM, from trailer manufacturers opposing averaging.

Specifically, the commenters cited their concern that the unique aspects of the trailer market tend to mean that the value of averaging as a tool is less than it has been for manufacturers in other industries, and the potential for negative consequences to some manufacturers is substantial. The trailer manufacturing industry is very competitive, and manufacturers must be highly responsive to their customers' diverse demands. Compared to other industry sectors, they can have little control over what kinds of trailer models their customers demand and thus limited ability to manage the mix and volume of different products. Additionally, one of the larger, more diverse manufacturers could potentially supply a customer with trailers that had few if any aerodynamic features, while offsetting this part of their business with over-complying trailers that they were able to sell to another customer; many smaller companies with limited product offerings might not be able to compete for those customers.

As a result of the many comments opposing averaging from trailer manufacturers—the very stakeholders meant to benefit from an averaging program—the agencies have reconsidered how averaging is incorporated into the program. The final program does not allow averaging as a compliance option in the early years of the program, in MY 2018 through MY 2026. In those years, all box vans sold (beyond a manufacturer's allowance of non-complying trailers) must meet the standards using any combination of available technologies.

However, the agencies have concluded that by late in the program, the value of an averaging option to many trailer manufacturers may well outweigh the concerns they have expressed. In addition, the final stage of the phase-in of the standards for MY 2027 represents the most stringent standards in the program, and additional flexibility may be welcome by trailer manufacturers. Therefore, the final program will provide a limited optional averaging program for MY 2027 and later full-aero box vans. By that time, we believe that the trailer manufacturers will be experienced and comfortable with the program, and the industry will be more familiar with the technologies.

The MY 2027 and later averaging provisions are identical in most respects to those we proposed for the other Phase 2 vehicle programs. One notable difference involves use of credits. As in the proposed trailer program, the averaging provisions for trailers focus on each individual model year's

production. A manufacturer choosing to use the averaging provisions could not “bank” compliance credits for a future model year or “trade” (sell) credits to another manufacturer, since these provisions would disproportionately benefit the few large trailer manufacturers. Under these averaging provisions, a full-aero box van manufacturer that produces some MY 2027 or later box vans that perform better than required by the applicable standard could produce a number of vans in the same family that do not meet the standards, provided that the average compliance levels of the trailers it produces in any given model year is at or below the applicable standards for that family.

As in the proposed program, averaging is only available for full-aero box vans. The program is already designed to offer reduced standards for box vans designated as partial-aero, and the additional flexibility of averaging is not available. Also, averaging is inherently incompatible with design standards for non-aero box vans and non-box trailers, since those manufacturers cannot choose among compliance paths.

The agencies are adopting averaging sets for full-aero box vans based on trailer length. Trailers in a family are certified to a single standard, but individual trailers within the family may be grouped to certify to a family emissions limit (FEL) that is higher or lower than the standard, provided the production-weighted average of all FELs in a family can be averaged to the standard or better. By allowing averaging sets to include both refrigerated and dry vans similar length categories, a manufacturer that over-complies, on average, in one family, can use the credits generated toward compliance in the other family. For example, if a manufacturer has two subfamilies in each of its long dry and long refrigerated van families, and the over-compliance of one dry van subfamily exceeds the under-compliance of the other dry van subfamily, the additional over-compliance beyond the dry van family's standard become credits that can be used to offset any under-compliance in the refrigerated van family.

In order to avoid backsliding with the use of averaging, the agencies are adopting a provision to require a minimum level of technology adoption in MY 2027 and later. No FEL can exceed the MY 2018 standard for the given trailer subcategory. For example, a manufacturer could not over-comply on some trailers and expect to produce a fraction of their trailers with zero

technologies installed; every trailer must, at minimum, include enough technologies to meet the corresponding MY 2018 standard. See 40 CFR 1037.107(a)(5) and 49 CFR 535.5(e).

As mentioned previously, manufacturers with a trailer family that performed better than the standard at the end of the year would not be allowed to bank credits for a future model year. However, the agencies understand that it is possible for a manufacturer to misjudge production and come up short at the end of the model year. In such a case, the program provides for a manufacturer to generate a credit deficit, if necessary, as a temporary recourse for unexpected challenges in a given model year.³⁷⁵ The agencies would closely monitor the certification applications for the following model year, to ensure the manufacturer can make progress in reducing the deficit. Any such credit deficits would need to be resolved within the following three model years, and the manufacturer would need to generate credits from over-compliance in subsequent years to address deficits from prior model years. See 40 CFR 1037.745.

The agencies believe that limiting the availability of averaging provisions to the final stage of the program will ease a number of the competitive concerns that trailer manufacturers have raised, since the trailer program will be familiar and the value of averaging may be greater as the most stringent standards phase in. Small business manufacturers raised concerns in our pre-proposal small business outreach that averaging would disproportionately benefit larger manufacturers with larger production volumes and greater product diversity. We are limiting our averaging program to single model year averaging (*i.e.*, no banking or trading) to help address this concern. Similarly, we are adopting a maximum FEL based on the MY 2018 standard to ensure that larger manufacturers will not be able to produce large volumes of trailers with little or no technologies at the expense of manufacturers that cannot accumulate sufficient over-compliance within their annual production. To the extent that concerns about the MY 2027 and later averaging provisions remain as that model year approaches, the agencies look forward to working with manufacturers as they consider using averaging.

³⁷⁵ Section IV.E.(1)(b) describes the process of identifying trailer families and sub-families based on basic trailer characteristics. 40 CFR 1037.710 describes the provisions for establishing subfamilies within a trailer family and the Family Emission Limits that are averaged among the subfamilies.

(c) Aerodynamic Device Testing Using SmartWay-Verified Data

The agencies expect some trailer manufacturers and aerodynamic device manufacturers to continue to submit test data to the SmartWay program for verification. Since many manufacturers have some experience with EPA's SmartWay program, the agencies have designed the trailer program and aerodynamic testing to recognize the significant synergy with the SmartWay Technology Program. Section IV.E.(3)(b)(v) describes the compliance path available to trailer manufacturers to use pre-approved performance data for aerodynamic devices. As an additional interim option, any device manufacturer that attains SmartWay verification for a device prior to January 1, 2018 is eligible to submit its previous SmartWay-verified data to EPA's Compliance Division for pre-approval, provided their test results come from one of SmartWay's 2014 test protocols that measure a delta C_dA . The protocols for coastdown, wind tunnel, and computational fluid dynamics analyses result in a C_dA value. Note that SmartWay's 2014 protocols allow SAE J1321 Type 2 track testing, which generates fuel consumption results, not C_dA values. Two commenters (a device manufacturer and an NGO) requested that we allow SAE J1321 track test results, but did not suggest a means of converting from the fuel consumption results to an appropriate delta C_dA value for use in compliance. As a result, the agencies will not accept J1321 data for pre-approval.

Beginning on January 1, 2018, EPA will require that device and trailer manufacturers that seek approval of new aerodynamic technologies for trailer certification use one of the approved test methods for Phase 2 (*i.e.*, coastdown, wind tunnel or CFD) and the test procedures found in 40 CFR 1037.526. Aerodynamic technologies that were pre-approved using performance data from SmartWay's 2014 Protocols will maintain their approved status through December 31, 2020. Beginning January 1, 2021, all pre-approval of device performance will need to be based on testing using the Phase 2 test procedures.

(d) Off-Cycle Technologies

The Phase 1 and Phase 2 programs include provisions for manufacturers to request the use of off-cycle technologies that are not recognized in GEM and were not in common use before MY 2010. During the development of the trailer proposal, the agencies were not aware of any technologies that could

improve CO₂ and fuel consumption performance that would not be captured in the trailer test protocols, and we did not propose a process to evaluate off-cycle trailer technologies. We continue to believe that effective trailer aerodynamic technologies that would not be captured by the test protocols are unlikely to emerge. However, Wabash provided comments requesting a process for evaluating future trailer weight reduction options. They suggested that these options could include lightweight components that are not listed in our regulations as approved material substitution components, or overall trailer weight reduction strategies that are not limited to individual components.

In light of these comments and further consideration of the issue, the agencies believe that the off-cycle technology process is an appropriate way for certain box van manufacturers—that is, those using the compliance equation and not subject to the design standards—to receive credit for future lightweighting or other technologies that are not recognized in the compliance equation. For this reason, we have incorporated box vans into the existing off-cycle provisions. In the case of lightweighting, a measured difference in trailer weight could substitute for the weight component of the compliance equation. For other such technologies (should any exist), the general off-cycle provisions apply. See 40 CFR 1037.515(e).

(e) Small Business Regulatory Flexibility Provisions

As a part of our small business obligations under the Regulatory Flexibility Act, EPA and NHTSA have considered additional flexibility provisions aimed at this segment of the trailer manufacturing industry. EPA convened a Small Business Advocacy Review (SBAR) Panel as required by the Small Business Regulatory Enforcement Fairness Act (SBREFA), and much of the information gained and recommendations provided by this process form the basis of the proposed flexibilities.³⁷⁶ As in previous rulemakings, our justification for including provisions specific to small businesses is that these entities generally have a greater degree of difficulty in complying with the

³⁷⁶ Additional information regarding the findings and recommendations of the Panel are available in Section XIV, Chapter 12 of the RIA, and in the Panel's final report titled "Final Report of the Small Business Advocacy Review Panel on EPA's Planned Proposed Rule: Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles: Phase 2" (See Docket EPA-HQ-OAR-2014-0827).

standards compared to other entities. Thus, as discussed below, we are adopting several regulatory flexibility provisions for small trailer manufacturers that we believe will reduce the burden on them while achieving the goals of the program.

The agencies identified 178 trailer and tank manufacturers for our analysis and we believe 147 qualify as small business (*i.e.*, less than 1000 employees).³⁷⁷ The agencies designed many of the program elements and flexibility provisions available to all trailer manufacturers with the large fraction of small business trailer manufacturers in mind. For the small van manufacturers, we believe the option to choose pre-approved aerodynamic data will significantly reduce the compliance burden and eliminate the requirement for all manufacturers to perform testing. We are also limiting the final non-box trailer program to tanks, flatbeds, and container chassis. All other non-box trailers are exempt from the Phase 2 trailer program, with no regulatory requirements. This exemption reduces the number of small businesses in the trailer program from 147 to 74 companies at the time of the development of this rulemaking. With no regulatory requirements, these companies have zero burden under the trailer program. We are also adopting the proposed design standards for the remaining non-box trailers, such that they can certify by installing tire technologies only, with no testing requirements. The agencies are also adopting provisions that would increase the number of eligible tire pressure systems that can be installed for compliance. In addition to ATIS, TPMS is a recognized technology in the final rulemaking. Furthermore, the non-box trailers, which have design-based tire standards, comply if they have either a TPMS or an ATIS, and appropriate lower rolling resistance tires. The inclusion of the less expensive TPMS as a tire pressure system option will improve the availability of technologies and reduce the technology cost for many small businesses.

As noted above, the small trailer manufacturers raised concerns that their businesses could be harmed by provisions allowing averaging, banking, and trading of emissions and fuel

consumption performance, since they will not be able to generate the same volume of credits as large manufacturers. The agencies are not adopting banking and trading provisions in any part of the program, and are limiting the option to average to manufacturers of full-aero dry and refrigerated box trailers and delaying the averaging until MY 2027. Similarly, we are adopting a maximum FEL based on the MY 2018 standard to ensure that larger manufacturers will not be able to produce large volumes of trailers with little or no technologies at the expense of manufacturers that cannot accumulate sufficient over-compliance within their annual production. We expect that the familiarity of the industry, including small business manufacturers, with the trailer program by this stage of the program, and the requirement that all trailers meet at least the MY 2018 level of control, will reduce the concerns of small manufacturer compared to an earlier or broader averaging program.

For all small business trailer manufacturers, the agencies are adopting a one-year delay in the beginning of implementation of the program, until MY 2019. We believe that this allows small businesses additional needed lead time to make the necessary staffing adjustments and process changes, and possibly add new infrastructure to meet the requirements of the program. TTMA commented that all trailer manufacturers are “small businesses” relative to other heavy-duty industries and that the one-year delay would divert sales to small businesses for that model year. Wabash argued that providing a flexibility is not required by the RFA and not authorized by the Clean Air Act. The agencies believe that small businesses do not have the same resources available to become familiar with the regulations, make process and staffing changings, or evaluate and market new technologies as their larger counterparts. We believe a one-year delay provides additional time for small businesses to address these issues, without a large CO₂ and fuel consumption impact or substantial negative competitive effects. The cumulative annual production of all of the small business box trailer manufacturers is estimated to be less than 15 percent of the industry’s total production, which is significantly less than the annual production of the four largest manufacturers.³⁷⁸ We expect any diverted sales for this one year will be

a small fraction of the large manufacturers’ production and we are finalizing the one-year delay for all small business trailer manufacturers.

Chapter 12 of the RIA presents the agencies’ Final Regulatory Flexibility Analysis. In this chapter, we discuss the recommendations of the Panel, what we proposed, and what we finalized for the small businesses regulated in Phase 2. We also estimate the economic effect of the rulemaking on these businesses based on their annual revenue. Considering the flexibilities adopted in this rulemaking, our estimate of compliance burden indicates that only 15 of the 147 small trailer manufacturers (about 10 percent) will have an economic impact greater than one percent of their annual revenue. Therefore, we believe the trailer provisions in this rulemaking do not have a significant impact on small businesses.

V. Class 2b–8 Vocational Vehicles

A. Summary of Phase 1 Vocational Vehicle Standards

Class 2b–8 vocational vehicles include a wide variety of vehicle types, and serve a wide range of functions. Some examples include service for urban delivery, refuse hauling, utility service, dump, concrete mixing, transit service, shuttle service, school bus, emergency, motor homes, and tow trucks. In the HD Phase 1 Program, the agencies defined Class 2b–8 vocational vehicles as all heavy-duty vehicles that are not included in the Heavy-duty Pickup Truck and Van or the Class 7 and 8 Tractor categories. In effect, the rules classify heavy-duty vehicles that are not a combination tractor or a pickup truck or van as vocational vehicles. Class 2b–8 vocational vehicles and their engines emit approximately 17 percent of the GHG emissions and burn approximately 17 percent of the fuel consumed by today’s heavy-duty truck sector.³⁷⁹

Most vocational vehicles are produced in a two-stage build process, though some are built from the “ground up” by a single entity. In the two-stage process, the first stage sometimes is completed by a chassis manufacturer that also builds its own proprietary components such as engines or transmissions. This is known as a vertically integrated manufacturer. The first stage can also be completed by a chassis manufacturer who procures all

³⁷⁷ In the period between the SBAR Panel and Initial Regulatory Flexibility Analysis and issuing of the final rule, the Small Business Administration (SBA) finalized new size standards for small business classification. For trailers, the threshold to qualify as small changed from 500 employees to 1000 employees. We have updated our analysis to reflect the new size standards.

³⁷⁸ See Figure 1–3 of Chapter 1 in the RIA comparing the 2015 trailer output from the top 28 trailer manufacturers.

³⁷⁹ Memorandum to the Docket “Runspects, Model Inputs, MOVES Code and Database for HD GHG Phase 2 FRM Emissions Modeling.” July 2016. See also EPA’s MOVES Web page at <https://www3.epa.gov/otaq/models/moves/index.htm>.

components, including the engine and transmission, from separate suppliers. The product completed at the first stage is generally either a stripped chassis, a cowed chassis, or a cab chassis. A stripped chassis may include a steering column, a cowed chassis may include a hood and dashboard, and a cab chassis may include an enclosed driver compartment. Many of the same companies that build Class 7 and 8 tractors also sell vocational chassis in the medium heavy- and heavy heavy-duty weight classes. Similarly, some of the companies that build Class 2b and 3 pickups and vans also sell vocational chassis in the light heavy-duty weight classes.

The second stage is typically completed by a final stage manufacturer or body builder, which installs the primary load carrying device or other work-related equipment, such as a dump bed, delivery box, or utility boom. There are over 200 final stage manufacturers in the U.S., most of which are small businesses. Even the large final stage manufacturers are specialized, producing a narrow range of vehicle body types. These businesses also tend to be small volume producers. In 2011, the top four producers of truck bodies sold a total of 64,000 units, which is about 31 percent of sales in that year.³⁸⁰ In that same year, 74 percent of final stage manufacturers produced less than 500 units.

The businesses that act both as the chassis manufacturer and the final stage manufacturer are those that build the vehicles from the “ground up.” These entities generally produce custom products that are sold in lower volumes than those produced in large commercial processes. Examples of vehicles produced with this build process include fire apparatus and transit buses.

The diversity in the vocational vehicle segment can be primarily attributed to the variety of customer needs for specialized vehicle bodies and added equipment, rather than to the chassis. For example, a body builder can build either a Class 6 bucket truck or a Class 6 delivery truck from the same Class 6 chassis. The aerodynamic difference between these two vehicles due to their bodies leads to different in-use fuel consumption and GHG emissions. However, the baseline fuel consumption and emissions due to the components included in the common chassis (such as the engine, drivetrain, frame, and tires) may be the same between these two types of vehicles.

Owners of vocational vehicles that are upfitted with high-priced bodies that are purpose-built for particular applications tend to keep them longer, on average, than owners of vehicles such as pickups, vans, and tractors, which are traded in broad markets that include many potential secondary markets. The fact that vocational vehicles also generally accumulate far fewer annual miles than tractors further contributes to lengthy trade cycles among owners of these vehicles. To the extent vocational vehicle owners may be similar to owners of tractors in terms of business profiles, they are more likely to resemble private fleets or owner-operators than for-hire fleets. A 2013 survey conducted by NACFE found that the trade cycle of private tractor fleets ranged from seven to 12 years.³⁸¹

The Phase 1 standards for this vocational vehicle category generally apply at the chassis manufacturer level. For the same reasons given in Phase 1, the agencies are applying the Phase 2 vocational vehicle standards at the chassis manufacturer level.³⁸²

The Phase 1 regulations prohibit the introduction into commerce of any heavy-duty vehicle without a valid certificate or exemption. 40 CFR 1037.622, originally codified as 40 CFR 1037.620, allows for a temporary exemption for the chassis manufacturer if it produces the chassis for a secondary manufacturer that holds a certificate. The agencies received several comments on the requirements for secondary manufacturers. A discussion of temporary exemptions and obligations of secondary manufacturers can be found in Section V.D.(2).

In Phase 1, the agencies adopted two equivalent sets of standards for Class 2b–8 vocational vehicles. For vehicle-level (chassis) emissions, EPA adopted CO₂ standards expressed in grams per ton-mile. For fuel efficiency, NHTSA adopted fuel consumption standards expressed in gallons per 1,000 ton-miles. The Phase 1 engine-based standards vary based on the expected weight class and usage of the vehicle into which the engine will be installed. We adopted Phase 1 vehicle-based standards that vary according to one key attribute, GVWR, based on the same groupings of vehicle weight classes used for the engine standards—light heavy-duty (LHD, Class 2b–5), medium heavy-duty (MHD, Class 6–7), and heavy heavy-duty (HHD, Class 8).

In Phase 1, the agencies defined a special regulatory category called

vocational tractor, which generally operate more like vocational vehicles than line haul tractors.³⁸³ As described above in Section III.C.4, under the Phase 1 rules, a vocational tractor is certified under standards for vocational vehicles, not those for tractors. In Phase 2, the agencies are revising the vocational tractor definition to remove heavy-haul tractors, as we are adopting tractor standards for these. The agencies received many comments pertaining to vocational tractors, which are described in Section III.C.4 and Section V.B.

Manufacturers are required to use GEM to determine compliance with the Phase 1 vocational vehicle standards, where the primary vocational vehicle manufacturer-generated input is the measure of tire rolling resistance. The GEM assumes the use of a typical representative, compliant engine in the simulation, resulting in one overall value for CO₂ emissions and one for fuel consumption. The manufacturers of engines intended for use in vocational vehicles are subject to separate Phase 1 engine-based standards. Manufacturers also may demonstrate compliance with the CO₂ standards in whole or in part using credits reflecting CO₂ reductions resulting from technologies not reflected in the GEM testing regime. See 40 CFR 1037.610.

In Phase 1, EPA and NHTSA also adopted provisions designed to give manufacturers a degree of flexibility in complying with the standards. Most significantly, we adopted an ABT program to allow manufacturers to comply on average within a given averaging set. See 40 CFR part 1037, subpart H. These provisions enabled the agencies to adopt overall standards that are more stringent than we could have considered with a less flexible program.³⁸⁴

B. Phase 2 Standards for Vocational Vehicles

Since proposal, in addition to considering substantive written public comments, the agencies have held dozens of meetings with manufacturers, suppliers, non-governmental organizations (NGOs), and other stakeholders to better understand the opportunities and challenges involved with regulating vocational vehicles. These meetings have helped us to better

³⁸³ See EPA's regulation at 40 CFR 1037.630 and NHTSA's regulation at 49 CFR 523.2.

³⁸⁴ As noted earlier, NHTSA notes that it has greater flexibility in the HD program to include consideration of credits and other flexibilities in determining appropriate and feasible levels of stringency than it does in the light-duty CAFE program. *Cf.* 49 U.S.C. 32902(h), which applies to light-duty CAFE but not to heavy-duty fuel efficiency under 49 U.S.C. 32902(k).

³⁸⁰ Specialty Transportation.net, 2012. Truck Body Manufacturing in North America.

³⁸¹ See 2013 ICCT Barriers Report, Note 364 above.

³⁸² See 76 FR 57120.

develop final Phase 2 standards. As an example, we have updated our industry characterization to better describe the vocational vehicle market, including the custom chassis manufacturers.³⁸⁵ We believe these information exchanges have enabled us to develop these rules with an appropriate balance of achievable reductions at reasonable cost with a reasonably small risk of unintended consequences.

(1) Final Subcategories and Test Cycles

The Phase 2 vocational vehicle standards are based on the performance of a wider array of control technologies than the Phase 1 rules. In particular, as proposed, the Phase 2 vocational vehicle standards recognize detailed characteristics of powertrains and drivelines. As described below, driveline improvements present a significant opportunity for reducing fuel consumption and CO₂ emissions from vocational vehicles. However, there is no single package of driveline technologies that will be equally suitable for the majority of vocational vehicles, because there is an extremely broad range of driveline configurations available in the market. This is due in part to the variety of build processes, ranging from a purpose built custom chassis to a commercial chassis that may be intended as a multi-purpose stock vehicle. Further, the wide range of applications and driving patterns of these vehicles leads manufacturers to offer a variety of drivelines, as each performs differently in use. For example, depending on whether the transmission has an overdrive gear, drive axle ratios for Class 7 and 8 tractors can generally be found in the range of 2.5:1 to 4.1:1. By contrast, across all types of vocational vehicles, drive axle ratios can range from 3.1:1 (delivery vehicle) to 9.8:1 (transit bus).³⁸⁶ Other components of the driveline also have a broader range of product in vocational vehicles than in tractors, including transmission gears, tire sizes, and engine speeds. Each of these design features affects the GHG emission rate and fuel consumption of the vehicle. It therefore is reasonable to define more than one baseline configuration of vocational vehicle, to

encompass a range of drivelines. A detailed list of the technologies the agencies project could be adopted to meet the vocational vehicle standards is described in Section V.C, and in the RIA Chapter 2.9, along with a description of the differences in technology effectiveness that are projected to be demonstrated through GEM under different test cycles. The agencies have found that the ranges of effectiveness of a majority of the technologies are significant enough to merit creation of subcategories with different test cycles.

(a) Basis for Duty Cycles and Subcategories

The agencies are relying on work conducted by the U.S. Department of Energy at the National Renewable Energy Laboratory (NREL), as well as duty cycle information provided in public comments, in establishing the weighting factors for the test cycles to be used in the certification of heavy-duty vocational vehicles to the final Phase 2 standards. NREL's methodology and findings are described in a report in the docket for this rulemaking.³⁸⁷ The data from NREL have also informed our segmentation process, and to some extent the technology assessment. For example, without data regarding the amount of parked idle observed by vocational vehicles in the NREL database, we would not have been able to sufficiently identify and recognize technologies that separately reduce either drive idle or parked idle emissions.³⁸⁸ Based on available fleet data, NREL identified three general clusters of vehicle behavior: one cluster of vehicles most often driving with slower speeds and frequent stops; one with higher average speeds and fewer stops; and one multi-modal cluster with vehicles that may operate similarly to either of the other clusters on any given day. In Chapter 2.2 of the NREL report, an alternate bi-modal clustering analysis is also presented, where instead of having a distinct middle cluster, vehicles with highly variable driving patterns are grouped as either high speed or low speed. A preliminary update provided by NREL includes cycle weightings that correspond with this two cluster depiction of vehicle

behavior.³⁸⁹ Based on the NREL report and other information, the agencies believe it is appropriate to finalize a regulatory subcategory structure that includes a drive cycle appropriate for mixed use vehicles; especially considering that the ultimate application of incomplete chassis is unknown at the time of certification. In other words, we are adopting a program structure that follows NREL's three cluster depiction of vehicle behavior. The final rules' primary vocational standards thus have subcategories for Regional, Multi-purpose, and Urban drive cycles in each of the three weight classes (LHD, MHD and HHD), which results in nine unique subcategories.

In the final weeks before promulgation, the agencies received significant new comments from a number of vehicle manufacturers, along with new data characterizing in detail the distribution of powertrain configurations of their vehicles.³⁹⁰ These recent comments suggested some uncertainty with respect to the three drive cycle structure, and the manufacturers expressed related concerns regarding assumptions about transmissions in our baseline vehicle configurations, which they believe could result in some OEMs being put at competitive disadvantage. The agencies appreciate these new comments and data; however, we determined that it would not be appropriate to alter this regulatory action so late in the rulemaking process based solely upon this newly submitted information, which was not made available for broader public comment. Instead, the agencies will continue to analyze this new information and any other new information we receive. We will also continue to actively engage with manufacturers and other stakeholders to determine if future revisions to the vocational vehicle program structure are warranted, based on this and any other new information. For example, it is possible that further analysis of new data could lead us to consider proposing amendments to adopt the two cluster approach for one or more of the vehicle weight classes, or to consider amending the regulatory constraints limiting the choice of drive cycle subcategory that we are adopting to prevent potential adverse impacts of vehicle misclassification. However, at this time the final program structure, including these constraints, will remain in place

³⁸⁷ National Renewable Energy Laboratory July 2016, "The Development of Vocational Vehicle Drive Cycles and Segmentation," NREL/TP-5400-65921.

³⁸⁸ While drive idle can generally be thought of as in-gear and parked idle can generally be thought of as out-of-gear, NREL has data on driving patterns for trucks with manual transmissions and has considered the fact that these are always out of gear when the vehicle has zero speed. See Section 5.5 of the final NREL report for more details.

unless and until the agencies determine that revisions to the vocational vehicle program structure are warranted, in which case the agencies would undertake a notice and comment rulemaking proposing to amend the programmatic structure, consistent with such a determination. In considering whether to undertake further action, the agencies will necessarily be mindful of statutory lead time requirements and other practical considerations.

NREL also synthesized a new transient test cycle using statistical targets and the DRIVE tool. Eaton commented that the new transient cycle developed by NREL is similar to cycles they use to calibrate shift controls, and is more representative of how trucks are driven than the current ARB Transient certification test cycle. Although there is some reason to believe this new cycle may actually be more representative of nationwide operation than the ARB transient cycle, the agencies recognize that sufficient uncertainty remains that we are not prepared to adopt this new NREL transient cycle for Phase 2 certification at this time. The agencies also note that, although GEM has been extensively validated for the ARB transient cycle, we have not conducted a similar validation for the NREL cycle. Nevertheless, we will continue to evaluate this cycle and may reconsider it as part of a future rulemaking. The most significant shortfall identified by NREL in their comparison of real world vocational vehicle operation and the ARB transient cycle is a gap in measurement points between speeds of 48 and 55 mph. We have remedied this shortfall by adjusting the composite weighting factor of the 55 mph cruise cycle. Because vehicles tested in GEM over our final road grade profile have been observed to decrease speed well below 55 mph during this cycle, those measurement points that are absent from the ARB transient cycle are captured in the nominally 55 mph test cycle.

Other commenters questioned whether the vehicles from which NREL collected data for the cycle were

sufficiently representative, or whether sufficient data existed to justify the NREL weightings, while other commenters supported use of the data. Daimler supported making changes to reflect the NREL-recommended weightings to align with real-world data. ACEEE supported using the more realistic NREL cycle weightings to revisit stringency where certain technologies may be more effective over the new cycles. Both Volvo and Navistar expressed concerns that the NREL study fleet doesn't appear to be representative. Navistar believes that the NREL data has too few refuse trucks, and Volvo believes that the NREL data has too few class 8 vehicles. In fact, 35 percent of the vehicles in the NREL database that were evaluated for the drive cycle analysis are class 8, which we believe is (if anything) *over-representative* of the percent of new HHD vehicles manufactured each year. Because the full NREL database also contains over five percent refuse trucks and our MOVES model estimates that refuse trucks comprise only three percent of newly manufactured vocational vehicles each year, we directed NREL to remove excess refuse trucks from their final analysis, to avoid skewing the data by over-representing refuse trucks.³⁹¹ A similar process was followed for removing excess school buses and transit buses. More details are available in the NREL report.³⁹² While some discrepancies may remain between the NREL vehicle distribution and the national fleet, we are confident they are sufficiently small to allow us to use this report to establish weighting factors for different types of operation. Moreover, the agencies believe the more relevant question to be whether or not the cycles exercise the technologies over enough of the range of in-use operation to effect in-use reductions, and to reasonably estimate the extent of those reductions. In this context, the weighting factors and duty-cycles are fully adequate.

After considering all the comments, the agencies are establishing nine subcategories of vocational vehicles in Phase 2, based on the three weight class

groups of vocational vehicles described above that are continuing from the Phase 1 program, plus Regional, Multipurpose and Urban duty cycle groups, as shown in Table V–1 below. For reasons described below in Section V.C.(2)(a) we are not establishing distinct subcategories for SI-powered vocational vehicles in the HHD weight class. Thus, with nine diesel subcategories and six gasoline subcategories, we are essentially setting 15 separate numerical performance standards. As described in Section V.B.2, we are also adopting optional standards for seven subcategories of custom vocational chassis.

This structure enables the technologies that perform best at highway speeds and those that perform best in urban driving to each be properly recognized over appropriate drive cycles, while avoiding unintended results of forcing vocational vehicles that are designed to serve in different applications to be measured against a single drive cycle. The agencies intend for these three drive cycles to balance the competing pressures to recognize the varying performance of technologies, serve the wide range of customer needs, and maintain reasonable regulatory simplicity. In light of the very recent comments noted above, if the agencies were to determine in the future that revisions to the vocational vehicle program structure are warranted, we would intend to propose any revisions in a way that would be consistent with the technology feasibility and cost-benefit analyses of this final rulemaking. In other words, the agencies do not anticipate any changes to the technology basis for, or the effective stringency of, the final standards. Rather, potential changes in program structure would only be to better assure that the projected reductions are achieved in use, consistent with the projected technology packages on whose performance the stringency of the final standards are based, and consistent with the costs we projected for that compliance pathway.

TABLE V–1—REGULATORY SUBCATEGORIES FOR VOCATIONAL VEHICLES

Duty Cycle	Regional Multi-Purpose Urban	Regional Multi-Purpose Urban	Regional. Multi-Purpose. Urban.

³⁹¹ MOVES 2014. See Note 379 above.

³⁹² National Renewable Energy Laboratory July 2016, “The Development of Vocational Vehicle Drive Cycles and Segmentation,” NREL/TP–5400–65921.

In the NREL Fleet DNA clustering analysis, the mediod of each cluster was characterized using eight drive cycle metrics, and distance histograms were created for each statistically representative vehicle. By summing the miles accumulated at different driving speeds (including zero speed idle), NREL was able to recommend composite cycle weightings. Commenters suggested that the proposed weightings of both highway cruise and idle were too low for some vehicles. When the agencies released additional data for comment in February 2016, an early draft of NREL's duty cycle report was included. Most commenters supported the draft NREL duty cycles. Volvo commented that NREL's cycle weightings didn't match their extensive telematics database for their class 8 vocational vehicles, and recommended specific changes to increase the weighting of 65 mph for Urban and Multipurpose HHD vehicles.

A description of the drive cycle data submitted to the agencies by Volvo in support of the final test cycles is found in the RIA Chapter 3.4.3.1. In response, we have adjusted our composite test weightings for Urban and Multipurpose HHD vehicles in consideration of Volvo's data. Although Volvo also suggested specific cycle weightings for coach buses, we have established optional coach bus standards (one example of the custom chassis standards the agencies are adopting) with the same weightings as for other Regional vehicles for reasons described below in V.B.2.b. The final cycle weightings shown in Table V-2 reflect NREL's recommendations along with consideration of public comments. Although both NREL and Volvo data showed vehicles whose behavior would logically be classified as Urban accumulating some miles (from one to seven percent) in the 65 mph range, the agencies are applying a zero weighting

factor to the 65 mph cycle for all Urban vehicles for certification purposes. Instead, those miles are assigned to the 55 mph cycle. We believe it is important to have a test cycle available in the primary program for vehicles that may regularly drive on urban or local highways, but are not expected (or designed) to drive on rural highways. Further, the final rules include the refinement of a split idle cycle (parked idle and drive idle), since NREL's final report includes analysis of data characterizing the percent of time in a work day that vocational vehicles idle when parked as distinct from idling time when stopped in traffic. More details on the characterization of parked and drive idle are found in the RIA Chapter 2.9.3.4. More details of the NREL clustering analysis are found in the RIA Chapter 2.9.2, and more details on the data behind the final composite cycle weightings are found in the RIA Chapter 3.4.3.

TABLE V-2—COMPOSITE TEST CYCLE WEIGHTINGS (IN PERCENT) FOR VOCATIONAL VEHICLES

	ARB transient	55 mph Cruise with road grade ^a	65 mph Cruise with road grade ^a	Parked idle	Drive idle
Regional	0.20	0.24	0.56	0.25	0.00
Multi-Purpose (2b-7)	0.54	0.29	0.17	0.25	0.17
Multi-Purpose (class 8)	0.54	0.23	0.23	0.25	0.17
Urban (2b-7)	0.92	0.08	0.00	0.25	0.15
Urban (class 8)	0.90	0.10	0.00	0.25	0.15

Note:

^a As described in Section II, the agencies have adopted highway cruise test cycles with revised road grade profiles.

We recognize that by adopting a few meaningful duty cycles that “bound” how vocational vehicles are generally used, we cannot perfectly match how every vocational vehicle is actually used. There are a few vehicle applications we have identified, for which these general cycles are likely to be poorly representative. We received several comments that our proposed duty cycles are particularly unrepresentative of real world behavior of transit buses and refuse trucks, for example. These vehicles also generally have chassis characteristics unlike those in the reference GEM vehicles used to establish the subcategory baselines. The agencies have determined that it is impractical, from a regulatory perspective, to establish separate, unique test cycles for transit buses or refuse trucks. In considering the challenges of such an undertaking, as well as the market structure of manufacturers who produce such vehicles, the agencies are instead adopting separate standards for transit buses and refuse trucks as part of the

final Phase 2 program for custom vocational chassis, as described in Section V.B.(2)(b).

Vocational vehicles neither qualifying under the optional custom chassis program nor meeting eligibility for exemption as low speed/off road vehicles will need to be certified in one of the primary subcategories established in this rulemaking. Below in Section V.C, the agencies explain the technology basis supporting the standards for each vehicle weight class.

The agencies received extensive comment on how to define attributes of vehicles in each subcategory to provide regulatory certainty to manufacturers. The proposed approach was to set criteria by which a vehicle manufacturer would know in which vocational subcategory—Regional, Urban, or Multipurpose—the vehicle should be certified, by use of cut-points defined using calculations relating engine speed to vehicle speed. Two commenters suggested we reinstate the Phase 1 approach with a one-size-fits-all drive cycle. Six commenters agreed with the

proposed approach on subcategorization, though some recommended slight adjustments. The final rules allow manufacturers to generally choose the subcategory of each vocational chassis, with a revised set of constraints essentially reflecting types of equipment on the vehicle (especially transmission type). In Section V.C.(2)(a) and the RIA Chapter 2.9, we describe changes since proposal with respect to the baseline vehicle configurations. In Section V.C.(2)(d), we describe the changes since proposal reflecting use of fleet average sales mixes in the standard-setting process. In Section V.D.(1)(e), we describe the constraints we are adopting regarding selection of subcategories by manufacturers. Taken together, these analyses demonstrate why we are confident that even if (generally against its own interests) a manufacturer chooses to certify a vehicle over a less appropriate test cycle, that choice would not result in a loss of environmental benefit. Continuing the averaging scheme from Phase 1, each manufacturer will

generally be able to average within each vehicle weight class (*i.e.* averaging sets are not further limited by the Regional, Multi-purpose, Urban subcategorization).

(b) Vocational Tractors

As discussed in Section V.A., the Phase 1 program includes a special regulatory category called vocational tractors, which covers vehicles that are technically tractors but generally operate more like vocational vehicles than line haul tractors. Heavy-haul, off-road, and certain intra-city delivery tractors are eligible for this category in the Phase 1 program, but manufacturers may also choose to certify them as conventional tractors. The agencies proposed to keep this program in Phase 2, but to exclude heavy-haul tractors. With the removal of heavy-haul tractors from the vocational tractor definition (see 40 CFR 1037.630 and 49 CFR 523.2), the agencies have re-assessed the vehicles remaining in this group, and the most appropriate way for them to be certified. One typically thinks of beverage tractors in this group, though it may also include drayage tractors, vehicle carriers, construction vehicles, and many vehicles with unusual axle configurations. NREL observed drayage tractors with operational patterns consistent with the Regional duty cycle.³⁹³ Volvo also commented that their vocational tractors would logically fall in the Regional duty cycle. The agencies have therefore concluded that these vehicles may reasonably be represented by our final regulatory duty cycles, and are requiring that vocational tractors not meeting other exemption criteria must use one of the vocational vehicle duty cycles.

There is a separate question of whether vocational tractors may have their performance fairly measured against the agencies' defined baseline vocational configurations. The agencies requested comment on whether vocational tractors would be deficit-generating vehicles if certified in the proposed vocational vehicle subcategories. When a vehicle is designed with a higher power engine or higher number of axles to carry a heavier payload than presumed in the GEM baseline for that subcategory, GEM may return a value that poorly represents the real world performance of that vehicle. We received comments from the chassis manufacturers who

certify vocational tractors, plus two other comments. These comments consistently asked the agencies to allow some tractors with GVWR over 120,000 lbs but not qualifying as heavy-haul tractors to remain as vocational vehicles rather than be forced to certify to the primary tractor standards. Volvo submitted written comments stating that a separate regulatory subcategory with unique performance standard is warranted for vocational tractors. However, during a subsequent telephone conversation, Volvo stated that their vocational tractors would be adequately represented by the other defined subcategories, and a unique subcategory was not necessary.³⁹⁴ See Section III.C.(4) for a discussion of the attributes adopted by the agencies as distinguishing vocational tractors from regular or heavy-haul tractors.

Based on comments and our technical analysis, the agencies have concluded that the technologies determined to be feasible for regular vocational vehicles are also feasible for vocational tractors, with similar adoption rates and package costs. Further, we are not aware of any non-diversified chassis manufacturers producing vocational tractors. One implication is that we believe that all manufacturers certifying vocational tractors will be able to take advantage of our ABT program flexibilities. According to MY 2014 certification data, less than 14,000 vocational tractors were certified between the three manufacturers, including an unidentifiable number that would likely qualify as heavy-haul tractors, if that definition existed in Phase 1. Thus, possible deficits (if any) generated by the small sales volume of vocational tractors in Phase 2 could likely be accommodated within each company's overall compliance plan.

(2) GHG and Fuel Consumption Standards for Vocational Vehicles

EPA is adopting CO₂ standards and NHTSA is adopting fuel consumption standards for manufacturers of chassis for new vocational vehicles. As described in Sections II.C.(1) and II.D.(1) above, the agencies are adopting test procedures so that engine performance will be evaluated within the GEM simulation tool. These test procedures include corrections for the test fuel, enabling vocational vehicles to be certified with many different types of CI and SI engines. In addition, EPA is establishing HFC leakage standards for air conditioning systems in vocational vehicles, as described in Section

V.B.(2)(c), with more details available in the RIA Chapter 2.9.3.8 and Chapter 5.3.4.

This section describes the standards and implementation dates that the agencies are adopting for the 15 regulatory subcategories of vocational vehicles, plus the optional standards for the seven custom vocational chassis categories. The agencies have performed a technology analysis to determine the level of standards that we believe will be available at reasonable cost, cost-effective, technologically feasible, and appropriate in the lead time provided. More details of this analysis are described in the RIA Chapter 2.9. This analysis considered the following for each of the regulatory subcategories:

- The level of technology that is incorporated in current new vehicles,
- forecasts of manufacturers' product redesign schedules,
- the available data on CO₂ emissions and fuel consumption for these vehicles,
- technologies that will reduce CO₂ emissions and fuel consumption and that are judged to be feasible and appropriate for these vehicles through the 2027 model year,
- the effectiveness and cost of these technologies,
- a projection of the technologically feasible application rates of these technologies, in this time frame, and
- projections of future U.S. sales for different types of vehicles and engines.

The final Phase 2 program described here and throughout the rulemaking documents is derived from the preferred alternative, referred to as Alternative 3 in the NPRM.

(a) Primary Fuel Consumption and CO₂ Standards

The agencies' final standards will phase in over a period of seven years, beginning in the 2021 model year, consistent with the requirement in EISA that NHTSA's standards provide four full model years of regulatory lead time and three full model years of regulatory stability, and provide sufficient time "to permit the development and application of the requisite technology" for purposes of CAA section 202(a)(2). The Phase 2 program will progress in three-year stages with an intermediate set of standards in MY 2024 and will continue to reduce fuel consumption and CO₂ emissions well beyond the full implementation year of MY 2027. The agencies have identified a technology path for each of these levels of improvement, as described below.

Combining engine and vehicle technologies, vocational vehicles powered by CI engines are projected to achieve improvements as much as 24

³⁹³ Comparing the vocational Regional duty cycle to the day cab tractor duty cycle, vocational Regionals have one percent greater weighting of the ARB Transient, 6 percent more weighting of the 55 cycle, 8 percent less weighting of the 65 cycle, plus 25 percent parked idle.

³⁹⁴ See call log for L. Steele, conversation with M. Miller, dated January 18, 2016.

percent in MY 2027 over the MY 2017 baseline, as described below and in the RIA Chapter 2.9. The agencies project up to 18 percent improvement in fuel consumption and CO₂ emissions in MY 2027 from SI-powered vocational vehicles, as shown in Table V–3. The

incremental Phase 2 vocational vehicle standards will ensure steady progress toward the MY 2027 standards, with improvements for CI-powered vehicles in MY 2021 of up to 12 percent and improvements for CI-powered vehicles in MY 2024 of up to 20 percent over the

MY 2017 baseline vehicles, as shown in Table V–3.

The agencies' analyses, as discussed in this Preamble and in the RIA Chapter 2, show that these standards are appropriate under each agency's respective statutory authority.

TABLE V–3—PROJECTED VOCATIONAL VEHICLE CO₂ AND FUEL USE REDUCTIONS (IN PERCENT) FROM 2017 BASELINE

Model year	Engine type	Heavy heavy-duty Class 8	Medium heavy-duty Class 6–7	Light heavy-duty Class 2b–5
2021	CI Engine	7–9	6–11	7–12
	SI Engine		5–7	6–8
2024	CI Engine	12–16	11–18	11–20
	SI Engine		9–12	9–14
2027	CI Engine	14–20	12–22	13–24
	SI Engine		10–16	11–18

Based on our analysis and research, and our consideration of the public comments, the agencies conclude that the improvements in vocational vehicle fuel consumption and CO₂ emissions can be achieved through deployment and utilization of a greater set of technologies than formed the technology basis for the Phase 1 standards. Further, since proposal, our assessment of technology effectiveness has changed primarily due to revisions in duty cycles and in some cases, the technologies themselves. The agencies received comments addressing the vocational vehicle standards broadly, including baselines, structure, and technologies. In response, in developing the final standards, the agencies have reevaluated the current levels of fuel consumption and emissions, the kinds of technologies that could be utilized by manufacturers to reduce fuel consumption and emissions, the associated lead time, the associated costs for the industry, fuel savings for the owner/operator, and the magnitude of the CO₂ reductions and fuel savings that may be achieved. After reexamining the possibilities of vehicle improvements, the agencies are basing the final standards on the performance of workday idle reduction technologies, improved transmissions including mild hybrid powertrains, axle technologies, weight reduction, electrified accessories, tire pressure systems, and further tire rolling resistance improvements. The EPA-only air conditioning standard is based on leakage improvements. These are largely the same technologies as we considered for the proposal, although some technologies that had been available only to tractors at proposal are now recognized for vocational vehicles. Our updated analysis shows that more

stringent standards than proposed are feasible, based in large part on our new assessment of the effectiveness of workday idle controls.

The agencies' evaluation indicates that some of the above vehicle technologies are commercially available today, though often in limited volumes. Other technologies will need additional time for development. Those that we believe are available today and may be adopted to a limited extent in some vehicles include improved tire rolling resistance, weight reduction, some types of conventional transmission improvements, neutral idle, and air conditioning leakage improvements. However, the first model year for the final Phase 2 standards will not be until MY 2021.³⁹⁵ As at proposal, the EPA continues to believe that any potential benefits that could be achieved by implementing rules requiring some technologies on vocational vehicles earlier than MY 2021 to be outweighed by several disadvantages. For one, manufacturers will need lead time to develop compliance tracking tools. Also, if the Phase 2 vocational vehicle standards began in a different year than the tractor standards, this could create unnecessary added complexity, and could strongly detract from the fuel savings and GHG emission reductions that could otherwise be achieved. Therefore the Phase 1 standards will continue to apply in model years 2018 to 2020. No commenter suggested otherwise.

Vehicle technologies that we expect will be available in the near term include neutral idle, low rolling resistance tires, improved axle

efficiency, and part-time 6x2 axles. Vehicle technologies that we have determined will benefit from even more development time to integrate engine and vehicle systems include stop-start idle reduction and hybrid powertrains. The agencies have analyzed the technological feasibility of achieving the fuel consumption and CO₂ standards, based on projections of what actions manufacturers may be expected to take to reduce fuel consumption and emissions to achieve the standards, and believe that the standards are technologically feasible throughout the regulatory useful life of the program. The basis for this finding is discussed below in Section V.C.3. EPA and NHTSA estimated vehicle package costs are found in Section V.C.(2).

Table V–4 and Table V–5 present EPA's CO₂ standards and NHTSA's fuel consumption standards, respectively, for chassis manufacturers of Class 2b through Class 8 vocational vehicles for the beginning model year of the program, MY 2021. As in Phase 1, the standards are in the form of the mass of emissions, or gallons of fuel, associated with carrying a ton of cargo over a fixed distance. The EPA standards are measured in units of grams CO₂ per ton-mile and the NHTSA standards are in gallons of fuel per 1,000 ton-miles. With the mass of freight in the denominator of this term, the program is designed to measure improved efficiency in terms of freight efficiency. As in Phase 1, the Phase 2 program assigns a fixed default payload in GEM for each vehicle weight class group (heavy heavy-duty, medium heavy-duty, and light heavy-duty). Even though this simplification does not allow individual vehicle freight efficiencies to be recognized, the general capacity for larger vehicles to carry more payload is represented in the

³⁹⁵ NHTSA is unable to adopt mandatory amended standards in those model years since there will be less than the statutorily-prescribed amount of lead time available. 49 U.S.C. 32902(k)(3)(A).

numerical values of these standards for each weight class group.

For each model year of the standards described below, the standards for vehicles powered by CI engines reflect improvements that correspond with performance of technologies projected to meet the separate CI engine standard in that year, as modeled over the GEM vehicle cycles. In other words, the CI vehicle standard directly reflects, and keeps pace with, the increasing stringency of the CI engine standard. As described above in Section II.D, the SI engine standard is remaining unchanged from Phase 1. However, the standards in each model year for vocational vehicles powered by SI engines are based in part on the performance of some additional engine technologies beyond what is required to meet the SI engine standards. In other words, certain SI engine improvements are reflected in the stringency of the SI vehicle standard.

EPA's vocational vehicle CO₂ standards and NHTSA's fuel

consumption standards for the MY 2024 stage of the program are presented in Table V-6 and Table V-7, respectively. These reflect broader adoption rates of vehicle technologies already considered in the technology basis for the MY 2021 standards. EPA's vocational vehicle CO₂ standards and NHTSA's fuel consumption standards for the full implementation year of MY 2027 are presented in Table V-8 and Table V-9, respectively. These reflect even greater adoption rates of the same vehicle technologies considered as the basis for the previous stages of the Phase 2 standards.

These standards are based on highway cruise cycles that include a final road grade profile that has been refined as a result of comment. This enables the standard and the GEM certification results to better reflect real world driving and to help recognize engine and driveline technologies while seeking to assure that technologies result in real world benefit. See the RIA Chapter 3.4.2.1.

As described in Section I, the agencies are continuing the Phase 1 approach to averaging, banking and trading (ABT), allowing ABT within vehicle weight classes. For Phase 2, continuing this approach means allowing averaging between CI-powered vehicles and SI-powered vehicles of any subcategory belonging to the same weight class group, which have the same regulatory useful life. However these averaging sets exclude vehicles certified to the separate custom chassis standards. Although we are further subdividing each vocational weight class group into Urban, Multi-Purpose, and Regional subcategories, we are not restricting credit exchanges between them. This is similar to the allowance to trade between vocational vehicles and tractors within a weight class. It is also consistent with the Phase 1 program, where the different types of vehicles within a weight class were included in a single averaging set.

TABLE V-4—EPA CO₂ STANDARDS FOR MY 2021 CLASS 2b-8 VOCATIONAL VEHICLES

Urban	36.0511	25.3438	26.4244
Multi-Purpose	32.4165	23.0845	22.5933
Regional	28.5855	21.4145	18.5658
NHTSA Standard for Vehicle with SI Engine Effective MY 2027 (Fuel Consumption gallon per 1,000 ton-mile)			
Duty cycle	Light heavy-duty Class 2b-5	Medium heavy-duty Class 6-7 (and C8 gasoline)	
Urban	46.4724	33.4196	
Multi-Purpose	41.8589	30.1564	
Regional	35.8951	27.7934	

As with the other regulatory categories of heavy-duty vehicles, NHTSA and EPA are adopting standards that apply to Class 2b-8 vocational vehicles at the time of production, and EPA is adopting standards for a specified period of time in use (*e.g.*, throughout the regulatory useful life of the vehicle). The derivation of the standards for these vehicles, as well as details about the provisions for certification and implementation of these standards, are discussed in more detail in Sections V.C. and V.D and in the RIA Chapter 2.9.

(b) Custom Chassis Fuel Consumption and CO₂ Standards

The agencies proposed a simplified compliance procedure and less stringent standards for emergency vehicles, while requesting comment on extending these flexibilities to other custom chassis such as recreational vehicles and buses. 80 FR 40292-40293. As described below, the agencies are finalizing a broader allowance that will also apply for vehicles other than emergency vehicles.

In response to the proposed provisions for emergency vehicles, we

received comments in support of adopting separate, less stringent standards for emergency vehicles through a simplified GEM process. Based on the reasoning set forth at proposal, and supported in the public comments, these final rules include optional emergency vehicle standards based on the same technologies as described in the proposal, and using a simplified version of GEM available through the custom chassis program. The use of a default engine in GEM avoids penalizing emergency vehicle manufacturers from installing engines that are likely to be credit-using engines against the separate engine standard, and avoids forcing emergency vehicles to be measured against an unrepresentative baseline over an unrepresentative drive cycle.

(i) Justification for an Expanded Custom Chassis Program

In the proposal, we requested comment on other manufacturers who could benefit from a similar regulatory approach, such as those offering such a narrow range of products that averaging is not of practical value as a compliance

flexibility, and for whom there are not large sales volumes over which to distribute technology development costs, as well as having drive cycles and functions that may make the primary standards either unrepresentative or unsuitable. Although this issue has some implications for our consideration of small business concerns, the custom chassis provisions discussed in the proposal were not intended to be limited to small businesses, and the final custom chassis standards are generally applicable (albeit optional). It is important to consider that for some vocational applications the custom-chassis manufacturers can have substantial market share. For example, Blue Bird is a manufacturer of school buses and school bus chassis with a substantial market share of its narrow product line.

We received comments in support of separate standards based on a different technology mix than the primary program for seven vocational vehicle applications. Gillig, New Flyer and Allison commented in support of separate standards for transit buses. RVIA, Newell Coach, Allison and Tiffin

Motor Homes commented in support of separate standards for motor homes. OshKosh commented in support of separate standards for cement mixers. Autocar and Volvo commented in support of separate standards for refuse trucks. Volvo and ABC Bus Companies commented in support of separate standards for motor coaches. Daimler and the School Bus Manufacturers Technical Council commented in support of separate standards for school buses.

The agencies received favorable comment on using a simplified compliance procedure for custom chassis from most commenters, but some expressed concerns. Autocar claimed that the simplified GEM interface would not sufficiently reduce the administrative compliance burden of small businesses, and recommended an engine-only certification method.

Custom chassis manufacturers that are not small businesses must comply with the Phase 1 standards and are generally doing so, by installing a mix of tires that, on average, meet the target coefficient of rolling resistance. Large manufacturers were not enthusiastic about offering a different approach for some vehicles, and urged that custom chassis standards, if adopted, be generally available as a compliance option. Based on public comment and extensive stakeholder outreach, the agencies have identified over a dozen chassis manufacturers serving the U.S. vocational market who produce a narrow spectrum of vehicles for which many technologies underlying the primary standards will either be less effective than projected, or are infeasible. Innovus commented that regulatory flexibility should only be offered to small volume producers who are also small entities. However, we do not believe it is warranted to force any of these specialized manufacturers to certify their narrow product line of vehicles to the primary standards, where stringency is premised on performance of some technologies unsuited for their specialized type of vehicle. Thus, the agencies have developed optional standards tailored for these vehicle types, and are not limiting eligibility to small entities.

Any manufacturer may certify their vehicles that we have identified as custom chassis vehicles under the primary standards. We expect that diversified chassis manufacturers selling a small number of their products into these defined custom applications could likely meet the primary Phase 2 standards on average, using internal credits. However, because the baseline configurations and duty cycles for these

custom applications would be less representative and some technologies would either be less effective or infeasible for them, these custom applications would likely be credit-using vehicles in the averaging set. Even so, we believe the primary Phase 2 standards are both feasible and appropriate for diversified manufacturers, as their broad mix of products allows them to average across their fleets, and some vehicles are likely to over-comply because their in-use applications are more compatible with the full range of available technologies. This is a feature of setting performance-based average standards with less than 100 percent adoption rates of technologies. Because we agree with commenters, including OshKosh who noted this is an expected market practice, we believe it is essential to not only set feasible targets for chassis manufacturers offering a narrow range of products and for whom fleet averaging will provide a smaller degree of compliance flexibility, but to also make this option available to diversified manufacturers. To address stakeholder concerns about large, diversified manufacturers having greater ability to produce credit-using vehicles than smaller, less diversified manufacturers, we are adopting additional flexibilities for manufacturers certifying to the custom chassis standards, including some flexibilities that will be available only for small businesses.

We do not view these standards as achieving less improvement than the primary program for these vehicles, and thus, we are not adopting any sales limits. Nevertheless, we requested comments on an appropriate sales volume that might be considered as a criterion to qualify for the numerically less stringent standards, where vehicle quantities above such sales threshold would need to be certified to the primary standards. We received comments from Allison, Autocar, Innovus, the School Bus Manufacturers Technical Council, and RVIA suggesting appropriate low-volume thresholds ranging from 200 to 26,000 vehicles per year. We received adverse comment from Daimler stating it would be unfair to make less stringent standards available solely on the basis of sales volume, because if a technology exists for one manufacturer, it is available to all manufacturers. We received adverse comment from OshKosh that less stringent regulations on a limited production volume stifles a custom chassis manufacturers' opportunity to grow their business. For each of the applications listed below in Table V-10,

the agencies have identified at least one manufacturer who produces chassis regulated under the Phase 2 program that are generally finished as a single vehicle type, as well as at least one competitor who is more diversified. After considering these comments, we continue to believe that no sales limits are needed.

After considering the comments on possible separate standards for custom chassis, the agencies have evaluated the feasibility of technologies for these vehicles on an application-specific basis. We shared draft custom chassis technology packages with affected stakeholders and received feedback.³⁹⁶ See Section V.C.1.a below discussing the feasibility of each technology as it applies for custom chassis vehicles. Section V.C.(2)(b) discusses the technology adoption rates from which the stringency of the optional custom chassis standards are derived.

Navistar commented with concerns that separate standards for custom chassis could create an unlevel playing field for manufacturers. ACEEE commented that the agencies should strengthen the primary vocational vehicle standard by one percent to offset the weaker standards for the custom chassis. ACEEE also commented that if chassis manufacturers can identify the vehicle application with enough specificity to take advantage of the custom chassis program, then they should also be able to take advantage of the most appropriate fuel-saving technologies, resulting in target stringencies that are not weaker than the main program. Although we agree that the custom chassis program should not result in a weakening of the overall vocational program, we disagree with ACEEE's recommendation to arbitrarily add back stringency. The agencies did not remove custom chassis in the final stage of a feasibility analysis of the primary program; rather, we separately considered the custom chassis vehicles as an integral part of developing the feasibility analysis in support of the final standards. The optional final standards are technology-advancing, appropriate, and maximum feasible for these applications. No arbitrary offset is needed or justified.

We disagree with claims made by commenters expressing concerns with respect to a shortfall or gap in emissions reductions between the primary vocational vehicle program and the custom chassis program. Some commenters have attempted to quantify

³⁹⁶ See record of Webinar on Vocational Custom Chassis, March 2016, Docket ID EPA-HQ-OAR-2014-0827-1944.

a difference in stringency by comparing select technology packages for custom chassis described in a February 2016 memorandum with the proposed technology packages for comparable subcategories.³⁹⁷ Because most of the baseline configurations for the custom chassis are tailored for each vocational vehicle, the only vehicle types where this comparison is straightforward is school buses and motor homes. In comparing the MY 2027 stringency of the medium heavy-duty Urban subcategory with the optional MY 2027 standard for school buses, for example, it can be seen that diesel vehicles in the primary program are projected to achieve 22 percent improvement on average, while school buses are expected to achieve 18 percent improvement on average. This is nowhere near the gap posited by certain commenters. Moreover, the difference in stringency reflects the reasonable conclusion that certain transmission technologies are not feasible for school buses.

This comparison is not straightforward for motor coaches and other custom chassis types, however, because the baselines are different and the vehicle attributes are not similar.

For example, our baseline configuration for coach buses includes a 350 hp 11-liter engine with a 6-speed automatic transmission. However, the primary program includes a baseline for heavy heavy-duty Regional vehicles that is a weighted average of 95 percent with 455 hp 15-liter engine with 10-speed manual transmission and 5 percent with a 350 hp 11-liter engine with a 6-speed automatic transmission. Due to the difference in performance of these configurations in GEM, a non-diversified coach bus manufacturer may find its fleet significantly “in the hole” in the first year of this program due solely to baseline differences. As an example of a technology difference, we have determined that regular HHD Regional chassis may reasonably apply AES on average at a rate of 90 percent by MY 2027, whereas we find that AES is not feasible at all for a conventional coach bus. A diversified manufacturer choosing to certify a coach bus in the HHD-R subcategory to the primary standards is likely to need to apply other technologies or use credits from other types of vehicles to meet the standard on average. A non-diversified coach bus manufacturer would be unlikely to achieve the HHD-R primary

program standard unless some very advanced technology is applied (at costs necessarily very different from those analyzed to be reasonable here). Therefore, we do not believe it is accurate to draw a comparison, as certain commenters maintained, between the HHD-R primary program stringency of 14 percent and the coach bus MY 2027 stringency of 11 percent.

Nonetheless, because these optional custom chassis standards are numerically less stringent than the primary Phase 2 vocational vehicle standards, the agencies are adopting a more restrictive approach to averaging, banking and trading (ABT), allowing averaging only within each subcategory for vehicles certified to these optional standards. Trading and banking will not be permitted except that small businesses certifying vehicles to these optional standards may use traded credits to comply. We are adopting these provisions to prevent generation of windfall credits against the less numerically stringent custom chassis standard. If a manufacturer wishes to generate tradeable credits from production of these vehicles, one or more families may be certified to the primary vocational vehicle standards.

TABLE V–10—CUSTOM CHASSIS POPULATION ESTIMATES

Application type	Percent of new MY 2018 vocational population	Average VMT in first year ^a
Coach (Intercity) Bus	1	85,000
Motor Home	13	2,000
School Bus	10	14,000
Transit Bus	1	64,000
Refuse Truck	3	34,000
Cement Mixer ^b	1	16,000
Emergency Vehicle ^c	1	6,000

Notes:

^a Source: MOVES 2014 for all except mixer and emergency.³⁹⁸

^b Source for cement mixer is UCS.³⁹⁹

^c Source for emergency is ICCT (2009)⁴⁰⁰ and FAMA (2004).⁴⁰¹

As shown in Table V–10, some of these vehicle types are produced in moderate volumes, and some are driven moderate distances annually. However, those that are produced in slightly higher volumes (motor homes and school buses) are among those driven the fewest miles. Similarly, those driven the most miles (coach and transit buses)

are among those produced in the smallest volumes. Collectively, the agencies estimate that the vehicles defined as custom vocational chassis in Phase 2 comprise less than 30 percent of the projected new vocational vehicle sales in MY 2018. Even so, because of the collectively small number of miles driven, the agencies believe that setting

less numerically stringent GHG and fuel consumptions standards for these vehicles will not detract from the greater benefits of this rulemaking, and that such separate standards are warranted in any case.

As proposed and discussed in the RIA Chapter 12, the agencies are adopting a provision for chassis manufacturers qualifying as small businesses to have

³⁹⁷ See memorandum dated February 2016 on Vocational Vehicle Technology Packages for Custom Chassis, Docket ID EPA–HQ–OAR–2014–0827–1719.

³⁹⁸ Vehicle populations are estimated using MOVES2014. More information on projecting populations in MOVES is available in the following report: USEPA (2015). “Population and Activity of

On-road Vehicles in MOVES2014—Draft Report” Docket No. EPA–HQ–OAR–2014–0827.

one extra year of lead time to comply with the initial Phase 2 standards.⁴⁰² Daimler stated it only supported additional lead time if it was provided equally to all custom chassis manufacturers. Because the SBA threshold in this sector is generally 1,500 employees, we believe that small entities have fewer in-house resources to collect and analyze compliance data than do manufacturers with more employees. Due to these resource constraints, the agencies believe it is appropriate to offer this only to small businesses—the entities that need further lead time. However, many custom chassis manufacturers do not qualify as small entities under the SBA regulations. We received comment from OshKosh that additional time to meet an impossible stringency target is not helpful, a comment addressed by adopting the separate custom chassis standards. The final program offers both a feasible standard, as described below, and additional lead time for small businesses.

Vehicles certifying to the optional custom chassis standards will be simulated in GEM using a default EPA engine map as well as many other EPA default parameters that are required inputs for vehicles in the primary program. While this is very similar to the Phase 1 GEM, more inputs are available in the Phase 2 custom chassis program than in Phase 1. Section V.D.(1) below describes the regulatory subcategory identifiers that must be input to GEM to call default vehicle specifications as part of obtaining valid simulation results for custom chassis in GEM.

The optional custom chassis standards will phase in over the same period as the primary vocational vehicle standards, beginning in the 2021 model year. However, there are no intermediate standards in MY 2024, so the optional MY 2021 custom chassis standards will continue until the full implementation year of MY 2027. The agencies have identified a technology path for each of these levels of improvement, as described below.

Combining engine and vehicle technologies, custom chassis are projected to achieve improvements from 6 to 18 percent in MY 2027 over the MY 2017 baseline, as summarized in Table V–11. The incremental standard in MY 2021 will achieve improvements of up to 10 percent over the MY 2017 baseline vehicles when including improvements

from MY 2021 diesel engines, as shown in Table V–11.

The agencies' analyses, summarized immediately below and discussed in detail in the RIA Chapter 2.9, show that these optional standards are justified under each agency's respective statutory authority. We note that for each model year of the Phase 2 custom chassis standards, the numerical value of the vehicle-level standard represents the performance of a diesel engine meeting that year's separate CI engine standard. Put another way, although the agencies are adopting distinct standards for custom chassis vocational vehicles, those vehicles must still use engines certified to the applicable Phase 2 engine standard. As in Phase 1, the chassis manufacturer is free to install any certified engine, and because GEM will run using a default map, the choice of engine will not affect the GEM result.

TABLE V–11—CUSTOM CHASSIS CO₂ AND FUEL USE REDUCTIONS (IN PERCENT) FROM 2017 BASELINE

Vehicle type	Model year	
	2021	2027
Coach Bus	7	11
Motor Home	6	9
School Bus	10	18
Transit	7	14
Refuse	4	12
Mixer	3	7
Emergency	1	6

It is worth noting that because the custom chassis version of GEM will not recognize certain technology improvements that some of these manufacturers will include based on market forces (after they have been introduced into the market as a result of the primary program), we expect actual in-use improvements for some of these vehicles to be slightly greater than is required by the standards. For example, we project that transmission manufacturers will improve the overall efficiency of their transmissions to enable vehicle manufacturers to comply with the primary standards. Once these transmissions have been developed and made available, we would not expect custom chassis manufacturers (or customers) to resist using them simply because they would not impact compliance with the standards.

(ii) GEM-Based Custom Chassis Standards

Table V–12 and Table V–13 present EPA's CO₂ standards and NHTSA's fuel consumption standards, respectively, for custom vocational chassis. The agencies have analyzed the

technological feasibility of achieving the fuel consumption and CO₂ standards, based on projections of actions manufacturers may take to reduce fuel consumption and emissions to achieve the standards, and believe that the standards are technologically feasible throughout the regulatory useful life of the program. EPA and NHTSA describe costs of the custom chassis standards in Section V.C.(2). In all cases we expect the technology package costs to be less than those of the primary Phase 2 standards, reflecting that the full set of technologies on which the stringency of the primary standards are based is not suitable for custom chassis applications. The costs of these standards are reasonable in the context of the reductions achieved, should be offset by fuel savings over the life of the vehicles.

These custom vehicle-level standards are predicated on a simpler set of vehicle technologies than the primary Phase 2 standard for vocational vehicles. (As already noted, these custom chassis vehicles will be required to use engines meeting the Phase 2 engine standards, and thus, should generally incorporate the same *engine improvements* as other vocational vehicles). In developing these optional standards, the agencies have evaluated the current levels of fuel consumption and emissions, the kinds of technologies that could be utilized by custom chassis manufacturers to reduce fuel consumption and emissions, the associated lead time, the associated costs for the industry, fuel savings for the owner/operator, and the magnitude of the CO₂ reductions and fuel savings that may be achieved. After examining the possibilities of vehicle improvements, the agencies are basing the optional vehicle-level standards for motor homes on adoption of TPMS and low rolling resistance tires. We are basing the optional standards for transit buses and refuse trucks on the performance of workday idle reduction technologies, tire pressure systems, simplified transmission improvements, and further tire rolling resistance improvements. The agencies are basing the standards for coach buses and school buses on all of the above technologies as well as simplified transmission improvements. The agencies are basing the standards for concrete mixers and emergency vehicles on use of tires with current average levels of rolling resistance. The EPA-only air conditioning standard is based on leakage improvements. Of these technologies, we believe that improved tire rolling resistance, neutral idle, and air conditioning leakage improvements

⁴⁰² See SBA regulations at 13 CFR 121.201. Thresholds effective February 2016 are available at <http://www.regulations.gov/#/documentDetail;D=SBA-2014-0011-0031>, 81 FR 4469.

are available today and may be adopted as early as MY 2021. As described in the RIA 2.9.3.4 and 2.9.5, the vehicle technology that we believe will benefit from more development time for engine and vehicle integration is stop-start idle reduction.

EPA's custom chassis CO₂ standards and NHTSA's fuel consumption standards for the full implementation year of MY 2027 reflect even greater adoption rates of the same vehicle technologies considered as the basis for the MY 2021 standards, described in more detail in Section V.C below.

As with the other regulatory categories of heavy-duty vehicles, NHTSA and EPA are adopting standards that apply to custom chassis vocational vehicles at the time of production, and EPA is adopting standards for a specified period of time in use (e.g., throughout the regulatory useful life of the vehicle). The derivation of the standards for these vehicles, as well as details about the provisions for certification and implementation of these standards, are discussed in more detail later in this document and in the RIA 2.9.3 to 2.9.6.

The optional standards shown below were derived using baseline vehicle models with many attributes similar to those developed for the primary program, with adjustments that are described below in Section V.C.(2)(a). Details of these configurations are provided in the RIA Chapter 2.9.2. For better transparency with respect to the incremental difference between the MY 2021 and MY 2027 vehicle standards, we have modeled a certified MY 2027 engine for both vehicle model years of optional custom chassis standards. Thus, chassis manufacturers who do not make their own engines may compare the two model years of standards presented in Table V-12 and Table V-13 and know that any differences are due solely to vehicle-level technologies.

TABLE V-12—EPA EMISSION STANDARDS FOR CUSTOM CHASSIS
[Gram CO₂/ton-mile]

	MY 2021	MY 2027
Coach Bus	210	205
Motor Home	228	226
School Bus	291	271
Transit	300	286
Refuse	313	298
Mixer	319	316
Emergency	324	319

TABLE V-13—NHTSA FUEL CONSUMPTION STANDARDS FOR CUSTOM CHASSIS

[Gallon per 1,000 ton-mile]

	MY 2021	MY 2027
Coach Bus	20.6287	20.1375
Motor Home	22.3969	22.2004
School Bus	28.5855	26.6208
Transit	29.4695	28.0943
Refuse	30.7466	29.2731
Mixer	31.3360	31.0413
Emergency	31.8271	31.3360

The agencies are adopting definitional provisions for each of the custom chassis subcategories to ensure that only eligible chassis will be able to certify to these numerically less stringent standards. The category with the most diversity and the greatest need for regulatory clarification is refuse. We received comments from OshKosh that there are seven distinct types of refuse trucks, including roll-on-roll-off vehicles, type T container haulers (hauling trailers containing waste), as well as residential front loaders, side loaders, and rear loaders. After considering these comments and other available information, we have determined that refuse trucks that do not compact waste are ineligible to certify to the custom chassis standards. For example, roll-off trucks do not engage in neighborhood waste collection and typically transfer full containers to and from regional landfills and construction sites. Furthermore, their driving patterns are more likely to resemble our Regional cycle than the Urban cycle. These trucks do engage in some PTO operation while parked when loading or unloading waste containers using hydraulically operated beds and possibly a winch or other onboard lift system; however, they do not use the PTO while driving. The relevant definitions and certification provisions for refuse and other vehicle types are discussed below in Section V.D.

As discussed above, we are not restricting the optional custom chassis program to small businesses, nor is there a production cap. Because we are allowing diversified manufacturers to certify some vehicles to the optional custom chassis standards, but some large manufacturers may not have a system for tracking what the final build of a vehicle is, we are adopting compliance procedures to assure that the final intended build will be one of the defined vehicle types. This approach is intended to level the playing field by allowing large manufacturers to choose this option

where their tracking (and/or controls imposed on the vehicle) is sufficient to know at the time of certification what the final build will be. This avoids restricting this path to a small subset of manufacturers.

(iii) Design Standards for Select Custom Chassis

The agencies are adopting an additional set of optional standards where manufacturers of motor home, cement mixer, and emergency vehicle chassis may elect to certify one or more families of vehicles to an equivalent standard. Certification would not require use of GEM if a manufacturer selects this option. Instead, certification using this option requires installation of specific technologies on every vehicle. This option does not allow any averaging, banking, or trading. These standards are equivalent in stringency to the GEM-based option for these three types of chassis. As mentioned above, the agencies received compelling public comment from Autocar suggesting that use of even the simplified GEM was unreasonably burdensome, and that further simplification was warranted in some cases. For small businesses especially, the certification burden of collecting data and running even a simplified version of GEM can present a disproportionately high burden, especially where there are very limited GEM inputs. Thus, the agencies sought to offer an option that minimizes the certification burden, recognizing the lesser complexity of the technology package associated with the standards for these chassis.

These equivalent technology-based standards are not available for manufacturers of coach bus, school bus, transit bus, and refuse truck chassis, as the technology packages for these chassis are more complex and cannot be projected to be installed at 100 percent adoption rates.

Table V-14 lists the technologies required to be applied to every vehicle sold by a manufacturer as part of a family certified to the optional non-GEM vocational vehicle standards. In addition, the vehicle must have a certified Phase 2 engine and comply with the separate standard to prevent leakage of HFC from the mobile air conditioning system. The combined tire CRR values shown in the table are obtained using Equation V-1.

Equation V-1 Vocational Tire CRR Level Formula
Steer tire CRR × 0.3 + Drive tire CRR × 0.7

Although manufacturers choosing this option will not have access to the

heavy-duty ABT program, this formula provides a small degree of freedom to

allow for some product variability while meeting the target for every vehicle.

TABLE V-14—OPTIONAL DESIGN (NON-GEM) STANDARDS

Vehicle type	Required technology	
	MY 2021	MY 2027
Motor Home	Combined CRR 6.7 kg/ton or less, and either TPMS or ATIS.	Combined CRR 6.0 kg/ton or less, and either TPMS or ATIS.
Emergency	Combined tire CRR 8.7 kg/ton or less	Combined tire CRR 8.4 kg/ton or less.
Mixer	Combined tire CRR 7.6 kg/ton or less	Combined tire CRR 7.1 kg/ton or less.

(c) HFC Leakage Standards

The Phase 1 GHG standards do not include standards to control direct HFC emissions from air conditioning systems on vocational vehicles. EPA deferred such standards due to “the complexity in the build process and the potential for different entities besides the chassis manufacturer to be involved in the air conditioning system production and installation.” See 76 FR 57194. During our stakeholder outreach conducted for Phase 2, we learned that the majority of vocational vehicles are sold as cab-completes with the dashboard-mounted air conditioning systems installed by the chassis manufacturer. For those vehicles that have A/C systems installed by a second stage manufacturer, EPA is adopting revisions to our regulations that resolve the issues identified in Phase 1, in what we believe is a practical and feasible manner, as described below in Section V.D.2.

EPA received comments generally supportive of adoption of A/C refrigerant leakage standards for Class 2b–8 vocational vehicles, beginning with the 2021 model year. Chassis sold as cab-completes typically have air conditioning systems installed by the chassis manufacturer. For these configurations, the process for certifying that low leakage components are used will follow the system in place currently for comparable systems in tractors. In the case where a chassis manufacturer will rely on a second stage manufacturer to install a compliant air conditioning system, the chassis manufacturer must follow the certifying manufacturer’s installation instructions to ensure that the final vehicle assembly is in a certified configuration.

(3) Exemptions and Exclusions

This section describes exemptions and exclusions related to vocational vehicles, including some that are available only in Phase 1 and some on which we asked for comment but did not adopt in the final program.

(a) Small Business Flexibilities

Although the Phase 1 program deferred the requirements for small businesses, the Phase 2 program will require small businesses to certify their affected vehicles. The RIA Chapter 12 presents a complete discussion of the outreach process that EPA conducted to solicit input from small businesses on the Phase 2 program. The RIA Chapter 12 explains why the agencies are adopting one year of additional lead time for all small businesses in Phase 2. Thus, the first compliance year for small entities is MY 2022 rather than MY 2021. The Small Business Advocacy Review Panel included representatives who produce vocational vehicle chassis, including emergency vehicles and concrete mixers. Discussions specific to vocational vehicle chassis during that process included exploration of a low volume production threshold below which some manufacturers may avoid some obligations of this regulation. Consistent with the recommendations of the Panel, the agencies requested comments on how to design a small business vocational vehicle program, including comments on a possible small volume threshold below which some small business exemption may be available.⁴⁰³ Innovus commented in support of a small volume threshold for vocational small businesses of either 200 vehicles per year or a different threshold set based on the market share of the entity. We received comments from Allison, Autocar, the School Bus Manufacturers Technical Council, and RVIA each suggesting different low-volume vocational chassis thresholds ranging as high as 26,000 vehicles per year. We received adverse comment from Daimler stating it would be unfair to make less stringent standards available solely on the basis of sales volume, because if a technology exists for one manufacturer, it is available to all manufacturers. We received adverse comment from OshKosh that less

⁴⁰³ See proposed rules at 80 FR 40295, July 13, 2015.

stringent regulations on a limited production volume stifles a custom chassis manufacturers’ opportunity to grow their business. Upon consideration of these comments, the agencies are not finalizing a broad sales volume threshold below which a vocational chassis manufacturer may reduce their compliance burden. Instead we are adopting the custom chassis program, and we are revising some of the exemptions that are carrying forward from Phase 1.

Autocar requested further consideration of the small business concerns of manufacturers of specialty vehicle applications, specifically recommending a low volume threshold if the agencies are not inclined to use a manufacturer’s business size as grounds for an exemption. Examples of specialty vehicles listed by Autocar include street sweepers, asphalt blasters, aircraft deicers, sewer cleaners, and concrete pumpers. Innovus also requested additional flexibility for meeting OBD requirements. Capacity Trucks commented that the terminal tractor industry is primarily comprised of small businesses who produce a total of less than 6,000 terminal tractors per year, 70 percent of which are fully off-road vehicles. See Section V.B.(3)(c) for a discussion of how we are addressing Innovus’ comment. See the discussion in Section V.B.(3)(b) for a discussion of how we are addressing the comments on vehicles that are off-road and low-speed.

(b) Off-Road and Low-Speed Vocational Vehicle Exemptions

In considering the above comments regarding additional vehicles that have significant operation at low speeds or off-road, the agencies are revising the exemptions adopted in Phase 1 for off-road and low-speed vocational vehicles at 40 CFR 1037.631 and 49 CFR 523.2. See generally 76 FR 57175.

These provisions already apply in Phase 1 for vehicles that are defined as “motor vehicles” per 40 CFR 85.1703, but may conduct most of their operations off-road, such as drill rigs, mobile cranes and yard hostlers.

Vehicles qualifying under these provisions must be built with engines certified to meet the applicable engine standard, but need not comply with a vehicle-level GHG or fuel consumption standard. To date, according to EPA records, vehicles exempted under this provision using the axle rating criterion included airport fire apparatus, airport service, fire service, oil field service, utility repair, refuse, and truck crane. Only two vehicles were exempted using the 45 mph speed criterion, however those also had rear axles with GAWR of 29,000 lbs. No vehicles were exempted under this provision using the 33 mph criterion. Two manufacturers exempted several vehicles under this provision using the 55-mph speed-limited tire criterion, including oil field, mining, construction, rock body, and fertilizer spreader applications.⁴⁰⁴ RMA commented that the agencies should not discontinue the speed-limited tire exemption criterion, as was proposed. However, their argument that it would be detrimental for a vehicle to drive above 55 mph with speed-limited tires is not compelling. It is too easy for a vehicle to be sold with speed-limited tires and subsequently have replacement tires fitted that are appropriate for higher speed operation. Although we are discontinuing the criterion for exemption based solely on use of tires with maximum speed rating at or below 55 mph, we are adding a new criterion whereby a vehicle qualifies to be exempted under this provision if it would exceed 95 percent of maximum engine test speed when traveling at 54 mph or with tamper-proof equivalent electronic controls. We are retaining the qualifying criteria related to design and use of the vehicle.

In considering the long list of specialty vehicle types raised by Capacity, Autocar and others, the agencies note that many of these may be primarily off-road vehicles in many respects, although some may not qualify as either off-road or low-speed under our regulations. In considering the drive cycle of those whose primary purpose is to transport an affixed device to an off-road work site for extended PTO operation, the agencies have concluded that the technologies we have determined to be feasible for concrete mixers are also feasible for this type of vehicle, and thus we are adopting a flexibility where vocational chassis that meet one of the two sets of criteria at 40 CFR 1037.631(a) (but not both) may be optionally certified under the custom chassis program to the standards

established for concrete mixers. These technologies include certified engines, low-leakage air conditioning components, and by MY 2027, steer tires with level 3V rolling resistance and drive tires with level 2v rolling resistance. We have similarly determined these technologies are feasible and reasonable to apply for vehicles whose primary purpose is to conduct work at slow speeds, but do not have affixed devices designed to be used at off-road work sites. This may include street sweepers and some terminal tractors.

We interpret the comments from Capacity to mean that many terminal tractors are produced in very small volumes by a large number of non-diversified small businesses. This is corroborated by comments from Autocar. Based on data from EPA's Smartway program, the drive cycles of some port drayage tractors can include a significant amount of highway time as well as idle time. According to available records, the average fraction of highway operation of 1,740 participating port dray tractors was 59 percent, and the average annual idle time was 762 hours.⁴⁰⁵ In considering this drive cycle information along with vehicle attributes, the agencies have determined that workday idle reduction technologies, transmission technologies, low rolling resistance tires, and other technologies factored into the primary vocational vehicle standards are feasible for drayage tractors that are not speed-limited. Therefore, the agencies believe that a standard reflecting performance of this type of technology package has potential applicability for this subset of drayage tractors. There is a competing consideration, however. As discussed above regarding our justifications for an expanded custom chassis program, we believe it is essential to set feasible targets for those chassis manufacturers who offer a narrow range of products. This is because fleet averaging provides a smaller degree of compliance flexibility for such manufacturers. Therefore we have determined that some type of alternative standard is warranted for non-diversified manufacturers who produce non-speed-limited drayage tractors. The transit bus custom chassis subcategory has a baseline with characteristics reasonably similar to drayage tractors, and is predicated on use of some but not all of the technologies that are feasible for drayage tractors. The agencies are adopting this as an alternative standard for non-speed-limited drayage tractors,

with one caveat. We are concerned that offering an optional standard based on adoption of fewer technologies than are actually feasible for drayage tractors could result in a loss of emission reductions that are technically feasible. To address this concern, the agencies are limiting the number of non-speed-limited drayage tractors that may be certified under the alternative standard.⁴⁰⁶ As stated above in Section V.B.(3)(a), Innovus commented that 200 vehicles per year would be an appropriate small volume threshold. Further, Autocar's written comments as well as information provided during follow-up meetings indicate that this threshold would accommodate their production of non-speed-limited drayage tractors. Therefore the agencies are adopting a flexibility exclusively for small businesses to optionally certify up to 200 drayage tractors annually under the custom chassis program to the standards established for transit buses. Otherwise manufacturers may elect to either certify their drayage tractors to the primary standards or design them to satisfy the eligibility criteria of 40 CFR 1037.631 (*i.e.*, to be speed-limited). We are adopting this as an interim provision (although there is no automatic sunset) to allow small businesses time to develop experience in the certification process as well as to develop future product plans.

(c) Specialty Vehicle Exemption

As described in Section XIII of this Preamble, the agencies are adopting alternate engine standards for specialty vehicles as part of the final Phase 2 program. Because some vocational vehicles may have engines certified under these specialty vehicle provisions found at 40 CFR 1037.605, we are clarifying here how these provisions interact. According to the regulations at 40 CFR 1037.605, a manufacturer may produce no more than 1,000 hybrid vehicles in a single model year under this option, and no more than 200 amphibious vehicles, speed-limited vehicles, or all-terrain vehicles. Under this provision, speed-limited vehicles are those that cannot exceed 45 mi/hr by tamper-proof calibration. Only vehicles with hybrid drivetrains that certify engines under this provision must also have a vehicle-level Phase 2 certificate, as required under 40 CFR 1037.105. The three other types would be exempt from the vehicle standards. Depending on the manufacturer and vehicle type, this may mean that such hybrid vehicles may need to meet the primary vocational

⁴⁰⁴ See memorandum dated July 2016 with data on exempted off-road vocational vehicles.

⁴⁰⁵ See memorandum dated July 2016 titled, "Summary of SmartWay Port Dray 2014 Data".

⁴⁰⁶ See Note 403, above.

vehicle standards or one of the custom chassis standards.

C. Feasibility of the Vocational Vehicle Standards

This section describes the agencies' technological feasibility and cost analysis. Further detail on all of these technologies can be found in the RIA Chapter 2.4 and Chapter 2.9. The variation in the design and use of vocational vehicles has led the agencies to project different technology solutions for each regulatory subcategory. Manufacturers may also find additional means to reduce emissions and lower fuel consumption than the technologies identified by the agencies, and of course may adopt any compliance path they deem most advantageous. This section includes discussion of the feasibility of the final standards for non-custom vocational vehicles using the full Phase 2 certification path, as well as the final optional standards for custom chassis standards.

NHTSA and EPA collected information on the cost and effectiveness of fuel consumption and CO₂ emission reducing technologies from several sources. The primary sources of information were the Southwest Research Institute evaluation of heavy-duty vehicle fuel efficiency and costs for NHTSA,⁴⁰⁷ the 2010 National Academy of Sciences report of Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles,⁴⁰⁸ TIAX's assessment of technologies to support the NAS panel report,⁴⁰⁹ the technology cost analysis conducted by ICF for EPA,⁴¹⁰ and the 2009 report from Argonne National Laboratory on Evaluation of Fuel Consumption Potential of Medium and Heavy Duty Vehicles through Modeling and Simulation.⁴¹¹

(1) What technologies are the Agencies considering to reduce the CO₂ emissions and fuel consumption of vocational vehicles?

In assessing the feasibility of the final Phase 2 vocational vehicle standards,

the agencies evaluated a suite of technologies, including workday idle reduction, improved tire rolling resistance, tire pressure monitoring or inflation systems, improved transmissions including hybrids, improved axles, improved accessories, and weight reduction, as well as their impact on reducing fuel consumption and GHG emissions. The agencies also evaluated aerodynamic technologies and full electric vehicles.

As discussed above, vocational vehicles may be powered by either SI or CI engines. The technologies and feasibility of the engine standards are discussed in Section II. At the vehicle level, the agencies have considered the same suite of technologies and have applied the same reasoning for including or rejecting these vehicle-level technologies as part of the basis for the final standards, regardless of whether the vehicle is powered by a CI or SI engine, since the vehicle level technologies are not a function of engine type. Generally, the analysis below does not distinguish between vehicles with different types of engines. The resulting vehicle standards do reflect the differences arising from the performance of CI (primarily diesel) or SI (primarily gasoline) engines over the GEM cycles. Note that vehicles powered by engines using fuels other than diesel or gasoline are subject to either the SI or CI vehicle standards, as specified in 40 CFR 1037.101.

(a) Vehicle Technologies Considered in Standard-Setting

The agencies note that the effectiveness values estimated for the technologies have been obtained using a variety of methods, including average literature values, engineering calculation, and GEM simulation. They do not reflect the potentially-limitless combination of possible values that could result from adding the technology to different vehicles. For example, while the agencies have estimated an effectiveness of one percent for e-accessories, each vehicle could experience a unique effectiveness depending on the actual accessory load for that vehicle. On-balance the agencies believe this is the most practicable approach for determining effectiveness for the technologies in the Phase 2 vocational vehicle program. This section is organized to first present the agencies' analyses of technology feasibility and effectiveness in Section V.C.(1), and below in Section V.C.(2) we present our projected technology adoption rates and estimated costs. Where other details are not given, the feasibility sections set forth our rationale for the projected

adoption rates. Average vehicle technology package costs by regulatory subcategory are presented below in Section V.C.(2)(e). Individual technology costs are summarized in the RIA Chapter 2.9.3, and full details behind all these costs are presented in RIA Chapter 2.11, including the markups and learning effects applied for each of the technologies.

(i) Transmissions

Transmission improvements present a significant opportunity for reducing fuel consumption and CO₂ emissions from vocational vehicles. Transmission efficiency is important for all vocational vehicles as their duty cycles involve significant amounts of driving under transient operation. Even Regional vocational vehicles have 20 percent of their composite score based on the transient test cycle. The three categories of transmission improvements the agencies proposed to consider as part of a compliance path used to determine standard stringency were driveline optimization, architectural improvements, and hybrid powertrain systems. As a result of comments and enhanced capabilities of GEM, we are adopting standards based on performance of a revised set of transmission technologies. For each technology, we have adjusted our projected penetration rates where we found that comments provided a persuasive reason to do so, and the effectiveness values are all updated according to the current GEM over the new drive cycle weightings.

The technology we described at proposal as driveline integration, 80 FR 40296, is now defined as use of an advanced shift strategy. At proposal the agencies included shift strategy, aggressive torque converter lockup, and a high efficiency gearbox among the technologies defined as driveline integration that would only be recognized by use of powertrain testing. We also proposed a 70 percent adoption rate in MY 2027 on the basis that this approach to improving fuel efficiency is highly cost-effective and technically feasible in a wide range of applications, and that the additional lead time would enable manufacturers to overcome barriers related to the non-integrated nature of businesses serving this sector. We received persuasive comments from manufacturers emphasizing the diversity of their product lines and the extent of testing that would be needed to apply this technology to 70 percent of their sales, and as a result we have reduced our projected adoption rates for this technology. The agencies continue to believe that an effective way to derive

efficiency improvements from a transmission is by optimizing it with the engine and other driveline components to balance both performance needs and fuel savings. One example of an engine manufacturer partnering with a transmission manufacturer to achieve an optimized driveline is the SmartAdvantage powertrain.⁴¹² The agencies project transmission shift strategies, including those that make use of enhanced communication between engine and driveline, can yield efficiency improvements ranging from three percent for Regional vehicles to nearly six percent for Urban vehicles, using engineering calculations (see RIA 2.9.3.1) to estimate the benefits that can be demonstrated over the powertrain test. We received comment that we had poorly defined the technology that can bring about improvements related to drive line integration. In considering the comments and available information, we believe it is reasonable to project that transmissions may feature advanced shift strategies where they make use of an additional sensor to improve fuel efficiency such as by detecting payload or road grade. See Section V.D.(1) and the RIA Chapter 3.6 for a discussion of the powertrain test procedure.

The agencies have revised the GEM simulation tool to recognize additional transmission technologies beyond what was possible at the time of proposal. We are adopting a transmission efficiency test to recognize improved mechanical gear efficiency and reduced transmission friction, where the test results can be submitted as GEM inputs to override the default efficiency values. Because this test can be conducted with a bare transmission without needing to be paired with an engine, each test will be valid for a much broader range of vehicle configurations than for a powertrain test. The agencies project vehicle fuel efficiency can be improved by up to one percent from improved transmission gear efficiency, which we are projecting to be the same during each of the driving cycles and zero while idling. RIA 2.9.3.1.1. Actual test results are likely to show that some gears have more room for improvement than others, especially where a direct drive gear is already highly efficient. Commenters requested that the minimum torque converter lockup gear be enabled as a GEM input without requiring powertrain testing. In response, final GEM also requires an input field for torque converter lockup gear. The baseline configurations with

automatic transmissions were run in GEM using lockup in third gear. The agencies project vehicle fuel efficiency can be improved up to three percent on a cycle average for torque converter lockup in first gear. RIA 2.9.3.1.1. Using the library of agency transmission files, GEM gives a different effectiveness value in every subcategory, because this is influenced by the gear ratios, drive cycle, and torque converter specifications. Manufacturers will obtain slightly different results with their own driveline specifications. The RIA at Chapter 2.9.3.1 includes a table that summarizes the various effectiveness values for different types of transmission improvements.

Although not factored into our stringency calculations, other non-hybrid transmission technologies that can also be recognized by powertrain testing include use of architectures not recognized by GEM such as dual clutch systems, and designs with reduced parasitic losses.

Most vocational vehicles currently use torque converter automatic transmissions (AT), especially in Classes 2b–6. Automatic transmissions offer acceleration benefits over drive cycles with frequent stops, which can enhance productivity. With the diversity of vocational vehicles and drive cycles, other kinds of transmission architectures can meet customer needs, including automated manual transmissions (AMT), dual clutch transmissions (DCT), as well as manual transmissions (MT).⁴¹³ As at proposal, dual clutch transmissions are simulated as AMT's in GEM. A manufacturer may elect to conduct powertrain testing to obtain specific improvements for use of a DCT. The RIA Chapter 4 explains the EPA default shift strategy and the losses associated with each transmission type, and discusses changes that have been made since proposal. Although the representation of transmissions has improved since proposal, the differences between AT and AMT are too difficult to isolate for purposes of figuring this into our stringency calculations. Although we expect manufacturers to have a reasonable model of transmission behavior for certification purposes, we could not estimate relative improvement values between AT and AMT for vocational vehicles using any defensible estimation method. The agencies have not been able to obtain conclusive data that could support a final vocational vehicle

standard, in any subcategory, predicated on adoption of an AMT or DCT with a predictable level of improvement over an AT. As a result, the only architectural changes on which the final vocational vehicle standards are based are increasing the number of gears and automation compared with a manual transmission.

The benefit of adding more gears varies depending on whether the gears are added in the range where most operation occurs. The TIAX 2009 report projected that 8-speed transmissions could incrementally reduce fuel consumption by 2 to 3 percent over a 6-speed automatic transmission, for Class 3–6 box and bucket trucks, refuse haulers, and transit buses.⁴¹⁴ We have run GEM simulations comparing 5-speed, 6-speed, 7-speed, and 8-speed automatic transmissions where some cases hold the total spread constant, some hold the high end ratio constant, and some hold the low-end ratio constant, where all cases use a third gear lockup and axle ratios are held constant. We have observed mixed results, with some improvements over the highway cruise cycles as high as six percent, and some cases where additional gears increased fuel consumption. As proposed, we are allowing GEM to determine the improvement, where manufacturers will enter the number of gears and gear ratios and the model will simulate the efficiency over the applicable test cycle. The agencies have revised GEM based on comment, and we are confident that it fairly represents the fuel efficiency of transmissions with different gear ratios. Consistent with literature values, we are using engineering calculations to estimate that two extra gears has an effectiveness of one percent improvement during transient driving and two percent improvement during highway driving. Weighting these improvements using our final composite duty cycles (zero improvement at idle), for purposes of setting stringency, we are conservatively estimating that adding two gears will improve vocational vehicle efficiency between 0.9 and 1.7 percent.

The final Phase 2 GEM has been calibrated to reflect a fixed two percent difference between manual transmissions and automated transmissions during the driving cycles (zero at idle). As in the HHD Regional subcategory baseline, manual transmissions simulated in GEM perform two percent worse than similarly-gearred AMT. This fixed

⁴¹³ See <http://www.truckinginfo.com/channel/equipment/article/story/2014/10/2015-medium-duty-trucks-the-vehicles-and-trends-to-look-for/page/3.aspx> (downloaded November 2014).

⁴¹⁴ See TIAX 2009, Table 4–48.

improvement is discussed further in the RIA Chapter 2.4.

Hybrid powertrain systems are included under transmission technologies because, depending on the design and degree of hybridization, they may either replace a conventional transmission or be deeply integrated with a conventional transmission. Further, these systems are often manufactured by companies that also manufacture conventional transmissions.

The agencies are including hybrid powertrains as a technology on which some of the vocational vehicle standards are predicated. We proposed ten percent overall adoption of strong hybrids by MY 2027, which meant approximately 18 percent adoption in the Multipurpose and Urban subcategories in that model year. 80 FR 40297. We received extensive comments on the ability of the vocational vehicle market to adopt hybrid drivetrains. EDF and Parker both highlighted the successful demonstrations of Parker hydraulic hybrids for refuse applications with effectiveness near 40 percent over refuse duty cycles. Autocar commented that a significant portion of their refuse truck sales have hydrostatic hybrid drives. Fleets such as Pepsico and the City of Bloomington highlighted that they are actively purchasing hybrids. ATA and UPS commented that hybrid technology applications continue to be of interest to the trucking industry, but expressed concern over the high costs that can deter uptake in the market. Eaton commented that a combination of factors is needed to re-ignite the hybrid business: lower battery costs and increased efficiency of the hybrid systems for Class 6–8, lower cost mild hybrid powertrains in Class 3–5, and continued regulatory pull. Eaton says the hybrid market is still very fragile and they do not see market conditions improving for hybrid commercial vehicles except for a few mild hybrids. Securing America's Future Energy and ACEEE also commented in favor of including mild hybrids as part of the vocational vehicle compliance package.

After considering all these comments, we agree with commenters that mild hybrids are more likely than strong hybrids to succeed initially in the vocational sector, especially outside of the bus market. We are projecting adoption of two types of mild hybrids, defined using system parameters based on actual systems commercially available in the market today.⁴¹⁵ NTEA

and the Green Truck Association both commented that a common way that today's hybrids are installed is by secondary or intermediate manufacturers. We have taken this into consideration by assuming that some mild hybrid systems will be integrated with an engine sufficient to enable use of an engine stop-start feature, while some mild hybrids will not be integrated and these "bolt-on" systems will only provide transient benefits related to regenerative braking.

Allison believes that hybrid vehicles should be certified on a duty cycle on the same basis as non-hybrid vehicles because the vehicles must perform the same work regardless of the powertrain technology. We agree and the Phase 2 test cycles are the same for conventional and hybrid drivelines. The Sierra Club asked the agencies to consider real world duty cycle data to account for the effectiveness of hybrids for vocational vehicles. Allison says investments for heavy-duty hybrids will be made by component suppliers, not by the vehicle manufacturers. The battery, inverter, and motor suppliers must make investments in addition to the system supplier. In this regard—for a small market like the heavy-duty hybrids—a significant investment, under current conditions, are seen as risky and unlikely to occur according to Allison. Allison commented that even though the transit bus industry has had commercially available hybrids for over a decade, the adoption rate of hybrids in the U.S. transit bus market is only 13.2 percent and that to achieve an overall 5 percent adoption rate of hybrid technology, the economics of the hybrid ownership would have to substantially change over the period of time covered by this rulemaking. In light of these concerns, we have adjusted our projected adoption rates of hybrid technology as described below in Section V.C.(2)(b)(i).

We also have reconsidered our effectiveness estimation method as a result of comments. Instead of relying on previously published road tests over varying drive cycles, we are applying engineering calculations to account for defined hybrid system capacities and inefficiencies over our certification test cycle. We are using a spreadsheet model that calculates the recovered energy of a hybrid system using road loads of the default baseline GEM vehicles over the ARB Transient test cycle. See RIA Chapter 2.9.3.1.3 to read more about the assumed motor and battery capacity, swing in the state of charge, and system

inefficiencies. The effectiveness is assumed (conservatively) to be zero for the highway cruise cycles to obtain the projected cycle-weighted effectiveness. For the non-integrated models, the same system was assessed for all weight classes (not scaled up for heavier vehicles); however, for the integrated models with stop-start we have scaled up the system specifications to account for the larger road loads, to ensure the projected effectiveness is not decreased for systems on heavier vehicles relative to that projected for lighter vehicles.

For the non-integrated mild hybrids, we are estimating an eight to 13 percent fuel efficiency improvement as measured over the powertrain test, depending on the duty cycle (*i.e.* Multi-purpose or Urban) in GEM for the applicable subcategory. See RIA 2.9.3.1. For the integrated mild hybrids, we have combined the effectiveness calculated for the scaled-up mild hybrid system with the effectiveness of stop-start, described below. *Id.* 2.9.3.1. These combined effectiveness values range from 18 to 21 percent efficiency improvement, depending on the duty cycle (*i.e.* Multi-purpose or Urban). Even though the actual improvement from hybrids in Phase 2 will be evaluated using the powertrain test, because the model uses the same vehicle test cycle and conservative estimates of realistic configurations, the agencies have concluded it is reasonable to use these spreadsheet-based estimates as a basis for setting stringency in the final rules.

Based on the public comments from hybrid suppliers and other innovators providing evidence of hybrid systems in the market today ranging from prototypes to commercialized, the agencies believe the Phase 2 rulemaking timeframes will offer sufficient lead time to develop, demonstrate, and conduct reliability testing for hybrid technologies to enable market adoptions in the range that we are projecting for the final rules.

The agencies are working to reduce barriers related to hybrid vehicle certification. In Phase 1, there is a significant burden associated with the optional test for demonstrating the GHG and fuel efficiency performance of vehicles with hybrid powertrain systems. If manufacturers wish to earn Phase 1 credit for a hybrid, they must obtain a conventional vehicle that is identical to the hybrid vehicle in every way except the transmission, test both, and compare the results.⁴¹⁶ In Phase 2,

⁴¹⁵ For example, see XL Hybrids at <http://www.xlhybrids.com/content/assets/Uploads/XL-BoxTruck-US-FLY-8.5x11-0519-LR.pdf>, and

Crosspoint Kinetics at <http://crosspointkinetics.com/members/kinetics-hybrid-partners/>.

⁴¹⁶ See test procedures at 40 CFR 1037.555. In Phase 1, evaluation of hybrid powertrain systems is

manufacturers will conduct powertrain testing on the hybrid system itself, and the results of that testing will become inputs to GEM for simulation of the non-powertrain features of the hybrid vehicle, removing a significant test burden. We will continue to work with hybrid suppliers and manufacturers to address other test burden issues, including test procedures to determine a balanced state of charge and number of default configurations needed for the cycle average map.

Hybrid manufacturers commented that meeting the on-board diagnostic requirements for criteria pollutant engine certification continues to be a potential impediment to adoption of hybrid systems. See Section XIII.A.1 for a discussion of regulatory changes to reduce the non-GHG certification burden for engines paired with hybrid powertrain systems. The agencies have also received comments on a letter from the California Air Resources Board requesting consideration of supplemental NO_x testing of hybrids.⁴¹⁷ Allison provided comment on CARB's recommendations, noting that it is not possible to draw conclusions about hybrid vehicles compared with conventional vehicles using the method recommended by CARB. Allison suggests that EPA gather additional data and conduct a future analysis based on data from both low-kinetic intensity and high kinetic intensity vehicles. In the final Phase 2 program, NO_x emissions will be measured and reported as a part of powertrain testing. This will allow EPA to monitor NO_x performance and identify potential problems long before sales increase to a point at which significant in-use impacts could occur. The information collected will also be used to inform EPA as to the merits of future rulemaking. However, EPA believes that finalizing the approach recommended at this time could represent an undue burden for this emerging technology.

Based on comments received and stakeholder outreach, we have reason to believe that some custom chassis manufacturers are better positioned than others to adopt transmission technology to improve fuel efficiency. Most have little or no in-house research capacity, and purchase off-the-shelf transmissions. Some, such as Gillig and Autocar, have partnered with suppliers to successfully implement hybrids on

their vehicles. Some bus chassis manufacturers are exploring the benefits of applying transmissions with additional gears. In real world driving, vehicles with a lot of transient operation, including custom chassis, can see real fuel savings from adoption of improved transmissions, including those with more efficient gears and advanced shift strategies. We expect that suppliers will continue to develop improved transmissions for vocational vehicles including some custom chassis, and that manufacturers will continue to select transmissions that deliver reliable products to fuel-conscious customers. Specifically, we believe that bus manufacturers will continue to have choices of competing products that offer performance characteristics that improve over time. Below in V.C.(2)(b) we discuss the reasons why we believe that a final Phase 2 program that is largely blind to these transmission-based improvements for custom chassis will avoid adverse unintended consequences.

(ii) Axles

The agencies are predicating part of the stringency of the final vocational vehicle standards on performance of two types of axle technologies. The first is advanced low friction axle lubricants and efficiency as demonstrated using the separate axle test procedure described in the RIA Chapter 3.8 and 40 CFR 1037.560. The agencies received adverse comment on the proposal to assign a fixed 0.5 percent improvement for this technology. In consideration of comments, the agencies are instead assigning default axle efficiencies to all vocational vehicles. Manufacturers may submit test data to over-ride axle efficiency values in GEM. Our cost analysis for the final rulemaking includes maintenance costs of replacing axle lubricants on a periodic basis. See the RIA Chapter 7.1.3. Based on supplier information, some advanced lubricants have a longer drain interval than traditional lubricants. We are estimating the axle lubricating costs for HHD to be the same as for tractors since those vehicles likewise typically have three axles. However, for LHD and MHD vocational vehicles, we scaled down the cost of this technology to reflect the presence of a single rear axle. We expect that improved axle efficiency is technically feasible on all vocational vehicles including custom chassis. However, it's likely that axle suppliers may be more likely to invest in design and lubrication improvements for high sales volume products, such as axles that can serve both tractor and vocational markets. Further, to the

extent that extreme duty cycles require lubricants with special performance features, it's likely that the most advanced low-friction lubricants may not be feasible for some custom chassis such as refuse trucks.

The second axle technology applies only for HHD vocational vehicles, which typically are built with two rear axles. Part time 6x2 configuration or axle disconnect is a design that enables one of the rear axles to temporarily disconnect or otherwise behave as if it's a non-driven axle. The agencies proposed to base the HHD vocational vehicle standard on some use of both part time and full time 6x2 axles. The agencies received adverse comment on the application of the permanent 6x2 configuration for vocational vehicles. The disconnect configuration is one that keeps both drive axles engaged only during some types of vehicle operation, such as when operating at construction sites or in transient driving where traction especially for acceleration is vital. Instead of calculating a fixed improvement as at proposal, the agencies have refined GEM to recognize this configuration as an input, and the benefit will be actively simulated over the applicable drive cycle. Effectiveness based on simulations with EPA axle files is projected to be as much as one percent for HHD Regional vehicles. Further information about this technology is provided in RIA Chapter 2.4.5. The feasibility of this technology depends on whether the baseline axle configuration is a 6x4 and whether the vehicle is likely to spend significant amounts of time on the highway. For vocational vehicles, this is largely limited to Regional and Multipurpose HHD vehicles. To the extent that any motor homes and coach buses with GVWR over 33,000 lbs are built with two rear axles, this technology could be technically feasible. However, because these vehicles generally operate on paved roads and may not need the traction of a 6x4, a popular axle configuration for these vehicles is a permanent 6x2.

(iii) Lower Rolling Resistance Tires

Tires are the second largest contributor to energy losses of vocational vehicles, as found in the energy audit conducted by Argonne National Lab.⁴¹⁸ The two most helpful sources of data in establishing the projected vocational vehicle tire rolling resistance levels for the final Phase 2 standards are the comments from RMA and actual certification data for model

an option for which advanced technology credits are available.

⁴¹⁷ California Air Resources Board. Letter from Michael Carter to Matthew Spears dated December 29, 2014. CARB Request for Supplemental NO_x Emission Check for Hybrid Vehicles. Docket EPA-HA-OAR-2014-0827.

⁴¹⁸ See Argonne National Laboratory 2009 report, Note 411, page 91.

year 2014. At proposal, we projected that all vocational vehicle subcategories could achieve average steer tire coefficient of rolling resistance (CRR) of 6.4 kg/ton and drive tire CRR of 7.0 kg/ton by MY 2027. These new data have informed our analysis to enable us to differentiate the technology projections by subcategory. The RMA comments included CRR values for a wide range of vocational vehicle tires, for rim sizes from 17.5 inches to 24.5 inches, for steer/all position tires as well as drive tires. The RMA data, while illustrating a range of available tires, are not sales weighted. The 2014 certification data include actual production volumes for each vehicle type, thus both steer and drive tire population-weighted data are available for emergency vehicles, cement mixers, school buses, motor homes, coach buses, transit buses, and other chassis cabs. The certification data are consistent with the RMA assessment of the range of tire CRR currently available. We also agree with RMA's suggestion to set a future CRR level where a certain percent of current products can meet future GEM targets. We disagree with RMA that the MY 2027 target should be a level that 50 percent of today's product can meet. With programmatic averaging, such a level would mean essentially no improvements overall from tire rolling resistance, because today when manufacturers comply on average, half their tires are above the target and half are below. Further, with Phase 2 GEM requiring many more vehicle inputs than tire CRR, manufacturers have many more degrees of freedom to meet the performance standard than they do in Phase 1. In these final rules, the agencies are generally projecting adoption of LRR tires in MY 2027 at levels currently met by 25 to 40 percent of today's vocational products, on a sales-weighted basis.⁴¹⁹ We are differentiating the improvement level by weight class and duty cycle, recognizing that heavier vehicles designed for highway use can generally apply tires with lower rolling resistance than other vehicle types, and will see a greater benefit during use. None of the rolling resistance levels projected for adoption in MY 2027 are lower than the 25th percentile of tire CRR on actual vocational vehicles sold in MY 2014. Thus, we believe the improvements will be achievable without need to develop new tires not yet available. Further

details are presented in the RIA Chapter 2.9.

In simulation, the benefit of LRR tires is reflected in GEM differently for vehicles of different weight classes and duty cycles. Based on simulations using the projected tire CRR, the agencies project fuel efficiency improvements by MY 2027 for LRR tires on Regional vocational vehicles between two and three percent, for Multipurpose vehicles between one and three percent, and for Urban vehicles up to one percent. This technology is also feasible on all custom chassis, with similarly larger improvements feasible for coach buses and motor homes with typically regional drive cycles, and similarly smaller improvements feasible for school and transit buses, refuse trucks, and concrete mixers with typically urban drive cycles.

As proposed, the agencies will continue the light truck (LT) tire CRR adjustment factor that was adopted in Phase 1. 80 FR 40299; see generally 76 FR 57172–57174. In Phase 1, the agencies developed this adjustment factor by dividing the overall vocational test average CRR of 7.7 by the LT vocational average CRR of 8.9. This yielded an adjustment factor of 0.87. Because the MY 2014 certification data for LHD vocational vehicles may have included some CRR levels to which this adjustment factor may have already been applied, and because we did not receive adverse comment on our proposal to continue this, the agencies have concluded that we do not have a basis to discontinue allowing the measured CRR values for LT tires to be multiplied by a 0.87 adjustment factor before entering the values in the GEM for compliance.

In Table V–15, the descriptors 1v through 5v refer to levels of rolling resistance that have been identified among the population of tires installed on vocational vehicles certified for MY 2014. Each of these levels is in production today and represents tires that have been fitted on a certified vehicle. The agencies have defined these levels for purposes of estimating the manufacturing costs associated with applying improved tire rolling resistance to vocational vehicles. These levels are not applicable for estimating degrees of improvement or costs of LRR tires on tractors, trailers, or HD pickups and vans as part of this rulemaking. Furthermore, these levels do not represent the full range of tire CRR available for vocational vehicles. There are both steer and drive tires on certified vocational vehicles today with CRR ranging from 5 kg/ton to 15 kg/ton. We expect this full range of tires will

continue to be available in the market well into the future.

TABLE V–15—DEFINED LEVELS OF VOCATIONAL TIRE CRR

Rolling resistance level descriptor	Range min.	Range max.
LRR level 1v	7.5	8.1
LRR level 2v	7.0	7.49
LRR level 3v	6.6	6.99
LRR level 4v	6.3	6.59
LRR level 5v	5.8	6.29

(iv) Workday Idle Reduction

The Phase 2 idle reduction technologies considered for vocational vehicles are those that reduce workday idling, unlike the overnight or driver rest period idling of sleeper cab tractors. Idle reduction technology is one type of technology that is particularly duty-cycle dependent. In light of new information, the agencies have learned that our proposal had mischaracterized the idling operation of vocational vehicles, significantly underestimating the extent of this mode of operation, and incorrectly calculating it using a drive idle cycle when significant idling also occurs while parked. As described above in Section V.B.(1), in these final rules we have revised our test cycles to better reflect real world idle operation, including both parked idle and drive idle test conditions. At proposal, we identified two types of idle reduction technologies to reduce workday idle emissions and fuel consumption for vocational vehicles: neutral idle and stop-start. After considering the new duty cycle information and the many comments received, we are basing our final vocational vehicle standards in part on the performance of three types of workday idle reduction technologies: neutral idle, stop-start, and automatic engine shutdown; which we believe are effective, feasible, and cost-effective, as discussed further in this section.

Neutral idle is essentially a transmission technology, but it also requires a compatible engine calibration. Torque converter automatic transmissions traditionally place a load on engines when a vehicle applies the brake while in drive, which we call curb idle transmission torque (CITT). When an engine is paired with a manual or automated manual transmission, the CITT is naturally lower than when paired with an automatic, as a clutch disengagement must occur for the vehicle to stop without stalling the engine. We did not receive adverse comment on our proposal to include this technology in our standard-setting for vocational vehicles. The engineering

⁴¹⁹ See memorandum dated May 2016 titled, Vocational Vehicle Tire Rolling Resistance Certification Data.

required to program sensors to detect the brake position and vehicle speed, and enable a smooth re-engagement when the brake pedal is released makes this a relatively low complexity technology that can be deployed broadly. Navistar commented that idle reduction strategies must have sufficient engine, aftertreatment and occupant protections in place such that any fuel cost savings are a net benefit for the owner/operator without compromising safety. We agree, and for neutral idle we believe an example of an allowable override is if a vehicle is stopped on a hill. Skilled drivers operating manual transmissions can safely engage a forward gear from neutral when stopped on upslopes with minimal roll-back. With an AT, the vehicle's computer would need to handle such situations automatically. In addition, engagement of the PTO while driving will be an allowable over-ride condition. In the Phase 2 certification process, transmission suppliers will attest whether the transmission has this feature present and active, and certifying entities will be able to enter Yes or No as a GEM input for the applicable field. The effectiveness of this technology will be calculated using data points collected during the engine test, and the appropriate fueling over the drive idle cycle and the transient cycle will be used. Based on GEM simulations using the final vocational vehicle test cycles, the agencies project neutral idle to provide fuel efficiency improvements up to seven percent for diesel vehicles, and up to two percent for gasoline vehicles, depending on the regulatory subcategory.⁴²⁰ The lesser effectiveness for gasoline vehicles is due to lower curb idle transmission torque present in the baseline configurations for gasoline than the diesel vehicles, as documented in the SwRI report.⁴²¹

Neutral idle may be programmed on any automatic transmission, and can reasonably be applied for vocational vehicles where this feature would not frequently encounter an over-ride condition. Vehicles with high PTO operation can apply this technology, although they would see reduced effectiveness in use.

Automatic engine shutdown (AES) is an engine technology that is widely available in the market today, but has seen more adoption in the tractor market than for vocational vehicles. Although we did not propose to include this technology, we received many

comments suggesting this would be appropriate. Some commenters may have conflated the concept of stop-start with AES, such as a comment we received asking us to consider the on-board need to power accessories while the vehicle is in stationary mode. We believe that automatic engine shutdown is effective and feasible for many different types of vehicles, depending on how significant a portion of the work day is spent while parked. Most truck operators are aware of the cost of fuel consumed while idling, and importantly, the wear on the engine due to idling. Engine manufacturers caution owners to monitor the extent of idling that occurs for each work truck and to reduce the oil change interval if the idle time exceeds ten percent of the work day.⁴²² Accordingly, many utility truck operators track their oil change intervals in engine hours rather than in miles.

NTEA provided the agencies with a report with survey results on which work truck fleets are adopting AES with backup power, and their reasons for doing so.⁴²³ The most common reason given in the survey is to allow an engine to shut down and still have vehicle power available to run flashing safety lights. Some vocational vehicles also need to conduct work using a power take-off (PTO) while stationary for hours, such as on a boom truck. The agencies are adopting an allowable AES over-ride for PTO use. Technologies that can reduce fuel consumption during this type of high-load idle are discussed below in V.C.(1)(c)(iii). We are also adopting an allowable AES over-ride if the battery state of charge drops below a safe threshold. This would ensure there is sufficient power to operate any engine-off accessories up to a point where the battery capacity has reached a critical point. Where a vocational vehicle has such extensive stationary accessory demands that an auxiliary power source is impractical or that an over-ride condition would be experienced frequently, we would not consider AES to be feasible. In the Phase 2 certification process, engine suppliers will attest whether this feature is present and tamper-proof, and certifying entities will be able to enter Yes or No as a GEM input for the applicable field.⁴²⁴ As with neutral idle described

above, the effectiveness of AES will be calculated in GEM using data obtained through engine testing. The appropriate data points over the parked idle cycle will be used for calculating the fueling. Based on GEM simulations using the final vocational vehicle test cycles, the agencies project AES to provide fuel efficiency improvements ranging from one to seven percent, depending on the regulatory subcategory.

The agencies proposed to predicate the vocational vehicle standards in part on 70 percent adoption of stop-start in MY 2027. We received numerous comments from manufacturers and suppliers with concerns about all aspects of this technology, including its feasibility, its effectiveness, and the lead time to make it commercially available. As discussed above, our assessment of workday idle reduction technologies has been refined since proposal, and part of this refinement includes less reliance on adoption of stop-start than at proposal.

Stop-start is a technology that requires an integration between engine and vehicle systems, and is seeing increasing acceptance in today's passenger vehicle market. The agencies are aware that for a vocational vehicle's engine to turn off during workday driving conditions, there must be a minimal reserve source of energy to maintain engine-protection and safety functions such as power steering, transmission pressure, engine lubrication and cooling, among others. As such, stop-start systems can be viewed as having a place on the low-cost end of the hybridization continuum. Effenco commented that a minimum of additional hardware is required to deliver enough power to frequently and seamlessly restart a large engine as well as to keep accessories and equipment operational with the engine turned off. Navistar commented persuasively that coking can occur if the cooling and lubricating oil is removed. The agencies therefore would consider electrified water and oil pumps to be part of the stop-start technology package. However, we must be clear to distinguish this technology from the AES described above. Stop-start technologies will be recognized only over the drive idle cycle and the transient cycle in GEM, not the parked idle cycle (whereas AES is recognized only over the parked idle cycle). Accordingly, the purpose of the additional hardware is to protect the engine for short duration stops such as at traffic lights, not to power accessories while the vehicle is parked.

Volvo commented that stop-start is not feasible for HHD engines (generally 11L and larger), and claims engine

⁴²⁰ See spreadsheet file dated July 2016 titled, "FRM_Vocational-Standards_GEMpostprocess.xls". See EPA-HQ-OAR-2014-0827.

⁴²³ NTEA, 2015 Work Truck Electrification and Idle Management Study.

⁴²⁴ We will consider non-tamper-proof AES as off-cycle technologies for a lesser credit.

development costs will be very high since stop-start cycling tests can only be accelerated by a limited amount before the failure mechanisms are altered. However, their objections relate more to the challenges of stop-start for HHD engines and do not actually show the technology to be infeasible. Although we disagree with Volvo that stop-start is infeasible for HHD engines, we understand it may require more development time and cost than for engines in lighter vehicles. It's possible that some time may be needed for development work where manufacturers elect to shift away from reliance on batteries for starting the engine and begin to rely instead on ultracapacitors, which do not have the same problems with cold weather operation and long term fatigue as do batteries.⁴²⁵ Volvo and EMA commented that main and rod bearings as well as other bearing surfaces would need to be strengthened and improvements may be needed for starters and lubrication systems. We agree with commenters that this type of development work would likely be part of bringing this technology to the vocational vehicle market, and thus we have included costs for upgrades similar to those described for all sizes of engines, not just those over 11L. In the event that an engine manufacturer needs to delay adoption of stop start to roll these changes in to a planned platform redesign, we believe our relatively modest adoption rate of 30 percent in MY 2027 will accommodate this. Descriptions of costs for stop-start may be found in the RIA Chapter 2.11.6.6.

We are not aware of stop-start systems that are commercially available for conventional vocational vehicles today, but this feature is available as part of some current hybrid systems. We are aware of one supplier who is demonstrating today a capacitor-based stop-start system with on-board electronics sufficient to protect a HHD engine and even power a PTO.⁴²⁶ Furthermore, other manufacturers and suppliers are researching this.⁴²⁷ Therefore we are confident heavy-duty stop-start systems for conventional vehicles will be feasible in the time frame of Phase 2. Where stop-start is relied upon as part of a certified configuration with components installed by a secondary manufacturer, these will be subject to specifications

and installation instructions of the certifying manufacturer.

In response to comments, we are adopting some permissible over-ride conditions under which a stop-start system may either restart sooner than otherwise or not shut down an engine. Navistar, Waste Management and others commented that vehicles with a significant power take-off (PTO) load will not be able to accommodate start/stop technology. As with neutral idle, we agree that engagement of the PTO while driving should be an allowable over-ride condition, as there are some vehicles that must conduct PTO work while underway. For example, cement mixers must continually rotate the drum and refuse trucks routinely compact their load throughout their neighborhood collection activity. Additional over-rides are discussed in the RIA Chapter 2.9.3.4. If a manufacturer designs a system that does not need as many over-rides due to additional electrification or other on-board systems, then an application for off-cycle credit may be submitted, to recognize a greater effectiveness. The regulations at 40 CFR 1037.660 specify the allowable over-rides.

The effectiveness of stop-start as recognized in GEM will be engine-dependent. Engines with high emissions/fuel consumption at idle will see greater reductions. Also, vehicles that idle frequently will see greater reductions. Based on GEM simulations using the final vocational vehicle test cycles, the agencies project stop-start to provide fuel efficiency improvements up to 14 percent for diesel vehicles, and up to 11 percent for gasoline vehicles, depending on the regulatory subcategory. See RIA 2.9.3.4. The data points for calculating the fueling over the transient and drive idle cycles are obtained from the engine map, and vehicle certifiers may input Yes or No when running GEM, to indicate whether the engine shuts off within five seconds of zero vehicle speed with the service brake applied. Allison commented that GEM should calculate fueling only for a couple seconds before assuming the engine shuts down in a stop-start system. Navistar suggested that we recognize that some fleets—e.g. heavy haul, refuse, mixer trucks and tow trucks—may elect to have this feature set as a programmable parameter to ensure maximum safety is maintained. We believe that five seconds is appropriate because we expect a wide variety of stop-start solutions to be deployed in the vocational vehicle market, and we anticipate modest use of over-ride conditions. Setting a shorter duration before shutdown could over-

estimate the reductions achieved by this technology in use. We believe this is a fair way to represent that the system may not have the designed effectiveness under all conditions.

As with the other idle reduction technologies described above, stop-start can reasonably be applied for vocational vehicles where this feature would not frequently encounter an over-ride condition. Vehicles with very little driving in transient conditions or with high PTO operation can apply this technology, although they would see reduced effectiveness in use. Chassis manufacturers certifying refuse trucks to the optional custom chassis standards may enter Yes in the input field in GEM for stop-start and the effectiveness will be computed based on the default 350 hp engine with 5-speed HHD automatic transmission. Manufacturers opting to certify refuse trucks to the primary standards will have an option to be recognized for enhanced stop-start systems through the powertrain test See RIA 2.9.3.4 and 2.9.5.1.4.

The agencies received comments from Allison Transmission where they observed a seven percent NO_x co-benefit of stop-start idle reduction technology on transit buses. Daimler also commented that it is investigating the potential for improving heat retention in the SCR system via stop-start, but because of early stages of development it cannot verify or quantify actual benefits. The agencies also conducted independent NO_x testing of engines at idle; however, the data are not conclusive enough for the agencies to quantify the NO_x co-benefits of vocational workday idle reduction as part of this rulemaking.

(v) Weight Reduction

The agencies are predicating the final vocational vehicle standards in part on use of material substitution for weight reduction. The method of recognizing this technology is similar to the method used for tractors. The agencies have created a menu of vocational chassis components with fixed reductions in pounds that may be entered in GEM when substituting a component made of a more lightweight material than the base component made of mild steel. According to the 2009 TIAX report, there are freight-efficiency benefits to reducing weight on vocational vehicles that carry heavy cargo, and tax savings potentially available to vocational vehicles that remain below excise tax weight thresholds. This report also estimates that the cost effectiveness of weight reduction over urban drive cycles is potentially greater than the cost effectiveness of weight reduction

⁴²⁵ Maxwell Technologies, How Ultracapacitors Improve Starting Reliability for Truck Fleets, 2016.

⁴²⁶ See comment submitted by Effenco describing such a system designed for a refuse packer.

⁴²⁷ See phone log for L. Steele, conversation with B. Van Amburg, May 2016.

for long haul tractors and trailers. We are adopting as proposed a GEM allocation of half the weight reduction to payload and half to reduced chassis weight. We did not receive comment suggesting a different weight allocation. The menu of components available for a vocational vehicle weight reduction in GEM is presented in Section V.D.1 and in the RIA Chapter 2.9, and is in the regulations at 40 CFR 1037.520. It includes fewer options than proposed, due to persuasive comments from Allison that aluminum transmission cases and clutch housings are standard for automatic transmissions. The American Iron and Steel Institute (AISI) commented that light weight values for high strength steel should be adjusted upward, citing light-duty vehicle weight reduction approaches using high strength steel and saying these improvements should apply to the heavy-duty sector as well. AISI also commented against the inclusion of any light-weight components as a compliance mechanism for vocational vehicles without technical data to support the weight saving values. At proposal, we based our weight reduction values for class 8 vocational vehicles on the values adopted for use in certifying tractors in Phase 1. We proposed to scale these values down for lighter weight vehicles based either on number of axles or other attributes based on engineering judgment. We also considered information supplied by expert members of the Aluminum Transportation Group.⁴²⁸ The final rules reflect revised weight reduction values in response to the comments from AISI, and in further consideration of information provided by the Aluminum Transportation Group. We were unable to make use of the additional references submitted by AISI as part of this standard-setting process, either because the technology requires redesign rather than material substitution, or because we did not see a way to apply the light-duty information to heavy-duty vehicles. For setting stringency, however, we do not rely on any values in the lookup table except those for aluminum wheels (although these performance-based standards may be achieved in the manner deemed most cost-effective by manufacturers). The stringency of the final vocational vehicle standards for custom chassis transit buses and vehicles in the primary program is based in part on use of aluminum wheels in 10 positions on 3-axle vocational vehicles (250 lbs) and in 6 wheel positions on 2-axle

vocational vehicles (150 lbs). Based on the TIAX report and experience with the tractor program, the agencies are confident that manufacturers who choose to incorporate weight reduction on vocational vehicles will have a number of feasible material substitution choices at the chassis level, which could add up to weight savings of hundreds of pounds. The agencies do not have information about any subset of vocational vehicles that would be unable to adopt aluminum wheels, thus our projected adoption rates are much higher than at proposal. Our projected adoption rate is revised upward based on the determination that the technology package is smaller (fewer pounds removed than at proposal) and that aluminum wheels are widely available and feasible. We have learned through stakeholder outreach that weight-sensitive applications such as ready-mix concrete and refuse have already extensively applied weight reduction technologies, for freight efficiency reasons.⁴²⁹ Therefore the agencies have not predicated the standards for these custom chassis on further weight reduction.

Based on the default payloads in GEM, and depending on the vocational vehicle subcategory, the agencies estimate a reduction of 250 lbs would offer a fuel efficiency improvement of up to one percent for HHD vehicles, and a reduction of 150 pounds would offer a fuel efficiency improvement up to 0.8 percent for MHD vehicles, and up to 1.5 percent for LHD vehicles. See RIA 2.9.3.5.

The agencies received comment that the HD Phase 2 program should recognize the enhanced benefit of weight reduction of rotating components, but the agencies lack sufficient data to incorporate the necessary programming in GEM to enable this feature. Manufacturers wishing to obtain credit for lightweight components beyond those on the menu in the regulations or for use of lightweighting technologies that are more effective than we have projected, may apply for off-cycle credits.

(vi) Electrified Accessories

Although we did not propose to allow pre-defined credit for electrified accessories as was proposed for tractors, we received comment requesting that this be allowed for vocational vehicles. As discussed above, the agencies are projecting that some electrified accessories will be necessary as part of

the development of stop-start idle reduction systems for vocational vehicles. The technology package for vocational stop-start includes costs for high-efficiency alternator, electric water pump, electric cooling fan, and electric oil pump. However, because the GEM algorithm for determining the fuel benefit of stop-start does not account for any e-accessories, vehicles certified with stop-start are also eligible to be certified using an improvement value in the e-accessories column.

Daimler, ICCT, Bendix, Gentherm, Navistar, Odyne, and CARB asked the agencies to consider electric cooling fans, variable speed water pumps, clutched air compressors, electric air compressors, electric power steering, electric alternators, and electric A/C compressors. ICCT cautioned that certain accessories would be recognized over an engine test and credit should not be duplicated at the vehicle level. Bosch suggested that high-efficiency alternators be considered, and suggested use of a standard component-level test for alternators to determine their efficiency, and establishment of a minimum efficiency level that must be attained. Although there are industry-accepted test procedures for measuring the performance of alternators, we do not have sufficient information about the baseline level performance of alternators to define an improved level that would qualify for a benefit at certification. We are not able to set a fixed improvement for electric cooling fans or clutched accessories due to similar challenges related to baselines and defining the qualifying technology. In consideration of ICCT's comment, we are not including water pumps and oil pumps among the components eligible for a fixed improvement because we believe that our engine test procedure will recognize improvements that would be seen in the real world from electrifying these. Thus, we believe it is appropriate to offer a fixed technology improvement for use of electric power steering and an electric A/C compressor as an input to GEM.

The agencies have conducted modeling in GEM to compare configurations with different default accessory loads, and have demonstrated there is a measurable effect of reducing 1 kW of accessory load for each vocational subcategory (see RIA 2.9.3.6). The agencies have incorporated information from this GEM modeling with information from comments provided by ICCT, the TIAX 2009 technology report, CARB's Driveline Optimization report, and the 2010 NAS report to assign fixed improvement values for the defined technologies as

⁴²⁸ See email to L. Steele from D. Richman dated March 19, 2015 with attachments.

⁴²⁹ See phone log for L. Steele, conversation with Terex (Aug 2015) and meeting with Autocar (April 2016).

shown in Table V–16. These values are consistent with the TIAX study that used 2 to 4 percent fuel consumption improvement for accessory

electrification, with the understanding that electrification of accessories will have more effect in short haul/urban applications and less benefit in line-

haul applications.⁴³⁰ The RIA Chapter 2.9 explains how these effectiveness values were obtained.

TABLE V–16—EFFECTIVENESS OF VOCATIONAL E-ACCESSORIES

Technology	Effectiveness %	Subcategories
Electric A/C Compressor	0.5 1.0	HHD. MHD & LHD.
Electric Power Steering	0.5 1.0	Regional. Multipurpose & Urban.

Optimization and improved pressure regulation may significantly reduce the parasitic load of the water, air and fuel pumps. Electrification may result in a reduction in power demand, because electrically-powered accessories (such as the air compressor or power steering) operate only when needed if they are electrically powered, but they impose a parasitic demand all the time if they are engine-driven. In other cases, such as cooling fans or an engine's water pump, electric power allows the accessory to run at speeds independent of engine speed, which can reduce power consumption. Electrification of accessories can individually improve fuel consumption, regardless of whether the drivetrain is a strong hybrid. Some vocational vehicle applications have much higher accessory loads than is assumed in the default GEM configurations. In the real world, there may be some vehicles for which there is a much larger potential improvement available than those listed above, as well as some for which electrification is not cost-effective. To date, accessory electrification has been associated only with hybrids, although CalStart commented they are optimistic that accessory electrification will become more widespread among conventional vehicles in the time frame of Phase 2.

Electric power steering (EPS) or Electrohydraulic power steering (EHPS) provides a potential reduction in CO₂ emissions and fuel consumption over hydraulic power steering because of reduced overall accessory loads. This eliminates the parasitic losses associated with belt-driven power steering pumps which consistently draw load from the engine to pump hydraulic fluid through the steering actuation systems even when the wheels are not being turned. EPS is an enabler for all vehicle hybridization technologies since it provides power steering when the engine is off. EPS is feasible for most vehicles with a standard 12V system.

Some heavier vehicles may require a higher voltage system which may add cost and complexity.

Manufacturers wishing to obtain credit for technologies that are more effective than we have projected, or technologies beyond the scope of this defined technology improvement, may apply for off-cycle credits.

(vii) Tire Pressure Systems TPMS

The agencies did not propose to base the vocational vehicle standards on the performance of tire pressure monitoring systems (TPMS). However, we received comment that we should consider this technology. See discussion in Section III.D.1.b. In addition to comments related to tractors and trailers, RMA commented that TPMS can also apply to the class 2b–6 vehicles, and if the agencies add TPMS to the list of recognized technologies, that this choice should also be made available to class 2b–6 vehicles. Bendix commented that TPMS is a proven product, readily available from a number of truck, bus, and motor coach OEMs. Autocar commented that TPMS is useful for refuse truck applications. Tirestamp said that TPMS is ideal for trucks and buses that are unable to apply ATIS due to difficulties plumbing air lines externally of the axles. The agencies find these comments to be persuasive. As a result, we are finalizing vocational vehicle standards that are predicated on the performance of TPMS in all subcategories, including all custom chassis except emergency vehicles and concrete mixers. Available information indicates that it is feasible to utilize TPMS on all vocational vehicles, though systems for heavy vehicles in duty cycles where the air in the tires becomes very hot must be ruggedized so that the sensors are protected from this heat. Such devices are commercially available, though they cost more. To account for this in our analysis, we have

projected a lower adoption rate for TPMS in Urban vehicles than for Regional or Multipurpose vehicles, rather than by increasing the cost and applying an equal adoption rate. We are assigning a fixed improvement in GEM for use of this technology in vocational vehicles of one percent for Regional vehicles including motor coaches and RV's (the same as for tractors and trailers) and 0.9 percent for Multipurpose, Urban, and other custom chassis vocational vehicles, recognizing that the higher amount of idle is likely to reduce the effectiveness for these vehicles. These values will be specified as GEM inputs in the column designated for tire pressure systems.

ATIS

The agencies did not propose to base the vocational vehicle standards on the performance of automatic tire inflation systems (ATIS), otherwise known as central tire inflation (CTI). However, we did receive comment indicating that it is feasible on some vocational vehicles. Air CTI commented that central tire inflation is not only feasible but enhances safety on vehicles such as dump trucks and heavy haul vehicles that need higher tire pressures under certain driving conditions, such as when loaded, but need lower tire pressures when running empty or operating off-road. Tirestamp commented that ATIS can be plumbed externally for trucks and buses, but such systems have a propensity for damage and Autocar has provided information about how much extra weight this plumbing adds to the chassis. ATA commented that some onboard air pressure systems may not be able to pressurize tires sufficiently for very heavy vehicles. The primary vocational vehicle standards are not predicated on any adoption of this because the agencies do not have sufficient information about which chassis will have an onboard air supply for purposes

⁴³⁰ TIAX 2009, pp. 3–5.

of an air suspension or air brakes. ATIS would logically only be adopted for vehicles that already need an onboard air supply for other reasons. Comments received for custom chassis were supportive of standards predicated on ATIS for buses with air suspensions. These comments are again persuasive. As a result, we are basing the optional standards for refuse trucks, school buses, coach buses, and transit buses in part on the adoption of ATIS. Although many motor homes have onboard air supply for other reasons making ATIS technically feasible, it is sufficiently costly that it is not practically feasible. Furthermore, for the same reasons stated above about the disadvantages of installing external plumbing for ATIS on some trucks and buses, we have determined it is not feasible for emergency vehicles or concrete mixers. Nonetheless, we are allowing vocational vehicles including all custom chassis to obtain credit for the performance of ATIS through a GEM input with a fixed improvement of 1.2 percent for Regional vehicles including motor coaches and RV's (the same as for tractors and trailers) and 1.1 percent for Multipurpose, Urban, and other custom chassis vocational vehicles, recognizing that the higher amount of idle is likely to reduce the effectiveness for these vehicles. These values will be specified as GEM inputs in the column designated for tire pressure systems. See discussion in Section III.D.1.b for our reasoning behind this effectiveness value.

(viii) HFC Refrigerant From Cabin Air Conditioning (A/C) Systems

Manufacturers can reduce direct A/C leakage emissions by utilizing leak-tight components. EPA's HFC direct emission leakage standard is independent of the CO₂ vehicle standard. Manufacturers may choose components from a menu of leak-reducing technologies sufficient to comply with the standard, as opposed to using a test to measure performance. See 76 FR 57194. A discussion of comments regarding use of low global warming potential refrigerants and EPA's responses to those comments can be found in Section I.F of this Preamble.

In Phase 1, EPA adopted a HFC leakage standard to assure that high-quality, low-leakage components are used in each air conditioning system installed in HD pickup trucks, vans, and combination tractors (see 40 CFR 1037.115). We did not adopt a HFC leakage standard in Phase 1 for systems installed in vocational vehicles. In the final Phase 2 program, as proposed, EPA is extending the HFC leakage standard to all vocational vehicles. Beginning in the 2021 model year, vocational vehicle

air conditioning systems with a refrigerant capacity of greater than 733 grams must meet a leakage rate of 1.50 percent leakage per year and systems with a refrigerant capacity of 733 grams or lower meet a leakage standard of 11.0 grams per year. EPA has determined that an approach of having a leak rate standard for lower capacity systems and a percent leakage per year standard for higher capacity systems will result in reduced refrigerant emissions from all air conditioning systems, while still allowing manufacturers the ability to produce low-leak, lower capacity systems in vehicles which require them.

Research has demonstrated that reducing A/C system leakage is both highly cost-effective and technologically feasible. The availability of low leakage components is being driven by the air conditioning program in the light-duty GHG rule which began in the 2012 model year and the HD Phase 1 rule that began in the 2014 model year. The cooperative industry and government Improved Mobile Air Conditioning program has demonstrated that new-vehicle leakage emissions can be reduced by 50 percent by reducing the number and improving the quality of the components, fittings, seals, and hoses of the A/C system.⁴³¹ All of these technologies are already in commercial use and exist on some of today's systems, and EPA does not anticipate any significant improvements in sealing technologies for model years beyond 2021. However, EPA has recognized some manufacturers utilize an improved manufacturing process for air conditioning systems, where a helium leak test is performed on 100 percent of all o-ring fittings and connections after final assembly. By leak testing each fitting, the manufacturer or supplier is verifying the o-ring is not damaged during assembly (which is the primary source of leakage from o-ring fittings), and when calculating the yearly leak rate for a system, EPA will allow a relative emission value equivalent to a 'seal washer' to be used in place of the value normally used for an o-ring fitting, when 100 percent helium leak testing is performed on those fittings.

We received comments from CARB and Daimler in support of applying these leakage standards to vocational vehicles. Daimler specifically expressed support for excluding A/C systems used to cool the cargo area of trucks, as well as for allowing helium testing as a compliance option. Thus, we are adopting these provisions as proposed. EMA commented with concerns about

the burden of certifying A/C systems that are installed by secondary manufacturers. Section V.D.2 discusses how we have addressed the concerns related to secondary manufacturers. We also received comments from RVIA asking for clarification whether the cargo area exclusion also applied to A/C units that cool the living space of recreational vehicles. In response, we are adding clarifying language to the regulations at 40 CFR 1037.115 excluding A/C systems that are not powered by the vehicle's propulsion engine.

The A/C system leakage control costs presented in the RIA Chapter 2.9 and 2.11 are applied to all heavy-duty vocational vehicles. EPA views these costs as minimal and the reductions of potent GHGs to be easily feasible and reasonable in the lead times provided by the final rules.

(b) Engine Technologies Considered in Vehicle Standard-Setting

Section II explains the technical basis for the agencies' proposed separate engine standards. The agencies are not predicated the vocational vehicle standards on different diesel engine technology packages than those presumed for compliance with the separate diesel engine standards. However, for each model year of the Phase 2 standards, the agencies are predicated the SI-powered vocational vehicle standards on a gasoline engine technology package that includes additional technologies beyond those presumed for compliance with the MY 2016 gasoline engine standard. Put another way, the stringency of certain of the vocational vehicle standards, and those for vehicles using SI engines in particular, reflect in part improvements in engine efficiency which are not measured in the engine standard or in engine certification.

The primary vocational vehicle standards vary depending on whether the engines powering those vehicles are compression-ignition or spark-ignition.⁴³² As in Phase 1, this is not the case for the custom chassis standards, because GEM uses a default engine that is the same for every regulated custom chassis type, regardless of the actual engine being installed. As described above in Section II, the Phase 2 vehicle certification tool, GEM, requires manufacturers certifying to the primary standards to enter specific engine performance data, where emissions and

⁴³¹ Team 1-Refrigerant Leakage Reduction: Final Report to Sponsors, SAE, 2007.

⁴³² Specifically, EPA is adopting CO₂, N₂O, and CH₄ emission standards for new heavy-duty engines over an EPA specified useful life period (See Section II).

fuel consumption profiles will differ significantly depending on the engine's architecture.⁴³³

As explained in Section II.A.2, engines will continue to be certified over the FTP test cycle via direct testing, not GEM simulation. The FTP test cycle that is applicable for bare vocational engines is very different than the test cycles for vocational vehicles in GEM. The FTP is a very demanding transient cycle that exercises the engine over its full range of capabilities. In contrast, the cycles evaluated by GEM measure emissions over more frequently used engine operating ranges. The ARB Transient vehicle cycle represents city driving, and the highway cruise cycles measure engine operation that is closer to steady state. Each of these cycles is described in the RIA Chapter 3.4.2. A consequence of recognizing engine performance at the vehicle level is that further engine improvements (*i.e.* improvements measureable by duty cycles that more precisely represent driving patterns for specific subcategories of vocational vehicles) can be evaluated as components of a technical basis for a vocational vehicle standard.⁴³⁴ For this reason, the agencies considered whether any different engine technologies should be included in the feasibility analysis for the vehicle standards (and potentially, in the standard stringency).

We did not propose to predicate any diesel vocational vehicle standard on additional engine technology, including engine waste heat recovery (WHR). We do not believe this technology would show significant benefit in vocational vehicle applications due to their driving cycles, which have fewer highway miles than tractors. Thus, the final vocational vehicle standards assume that diesel engines perform at the level of the certified engine configuration.

The agencies received extensive comment on our assessment of SI engine technologies, and how these could be included in the vocational vehicle technology packages. We predicated the proposed MY 2027 SI-powered vocational vehicle standards on additional friction reduction, for a 0.6 percent fuel efficiency improvement. UCS, EDF, NRDC, and ICCT ask the agencies to rely on the 2015 SwRI study suggesting 8 percent improvement is possible. UCS highlights packages #16 and #22 of the SwRI report for the

agencies' further consideration. These packages were assembled by SwRI to simulate the combined performance of engine technologies over some well-known vehicle drive cycles. Because none of the technical data referenced by these commenters provides information on how these technologies perform over the HD gasoline engine FTP test procedure, the agencies are considering these to be comments on the GEM-based vocational vehicle standards, not comments on the separate FTP-based SI engine standard. Please see Section II.D.2(b) of this Preamble for the agencies' response to comments on the stringency of the separate SI engine standard.

SwRI package #16 applies variable valve actuation and exhaust gas recirculation to a 3.5 liter V6 engine. SwRI package #22 applies stoichiometric direct gas injection, exhaust gas recirculation, dual cam phasers, and advanced friction reduction to a 6.2 liter V8 engine. All of the SwRI packages compare the future vehicle performance to a pre-Phase 1 baseline, thus counting all the improvements already presumed in the MY 2016 engine standard, so the delta between what the commenter seeks and what the agencies proposed is considerably less than initially appears (and than the commenter appeared to believe). The agencies' default SI engine map for setting the SI-powered vocational vehicle standards is a MY 2016 6.8 liter V8 engine. The RIA Chapter 2.9.1 presents the EPA default map that meets the MY 2016 engine standard. We are adhering to the proposed approach of recognizing SI engine improvements only in the vocational vehicle standard. In response to comments, the agencies are adopting final vehicle-level standards for SI-powered vocational vehicles that are predicated in part on adoption of cylinder deactivation in addition to the advanced friction reduction reflected in the proposal, both of which have incremental costs beyond those needed to meet the separate FTP-based engine standard, and both of which will be recognized over the GEM vehicle cycles. Indeed, cylinder deactivation would not be expected to be recognized at all over the engine FTP cycle (another reason the improvement is reflected in the final vehicle standard). As proposed, the effectiveness and adoption rate of Level 2 engine friction reduction yields a fuel efficiency improvement of 0.6 percent. By adding 30 percent adoption of cylinder deactivation with a vehicle-cycle average effectiveness of 1 percent, and accounting for a dis-synergy factor

of 0.9, this yields an overall package effectiveness of 0.8 percent. Upon consideration of comments and the data in the SwRI reports, we are not including EGR as a technology for stringency purposes. EGR is potentially feasible, is not already presumed to be adopted in the 2016 engine standard, and may possibly be recognized over the GEM vehicle cycles to some extent. However, we did not have sufficient data to confidently project an effectiveness or adoption rate for this technology on vocational SI engines. Further, the Phase 2 HD pickup truck and van standards are not predicated on any adoption of EGR technologies for SI vehicles. The RIA Chapter 2.9.1 describes how each of the SI engine technologies are expected to perform over the GEM vehicle cycles, as well as the method for projecting that the fuel efficiency improvement will be 0.8 percent compared to the baseline SI vehicle performance.

With respect to standards for engines used in custom chassis, we understand that engines designed for heavy-duty emergency vehicles are generally higher-emitting than other engines. However, because we are maintaining a separate engine standard and regulatory flexibility such as ABT, fire apparatus manufacturers will be able to obtain engines that, on average, meet the Phase 2 engine standards. The agencies further recognize that the engine map inputs to GEM in the primary program could pose a difficulty for emergency vehicle manufacturers. If we required engine-specific inputs then these manufacturers will have to apply extra vehicle technologies to compensate for the necessary but higher-emitting engine. The agencies are therefore not recognizing vehicle-specific engine performance as part of the vehicle standard for emergency vehicles (although the standards for emergency vehicles and custom chassis do presume use of a certified Phase 2 engine). Manufacturers of these vehicles must install an engine that is certified to the applicable separate Phase 2 engine standard. However, under the custom chassis program emergency vehicle manufacturers need not follow the otherwise applicable Phase 2 approach of entering an engine map in GEM. Instead, use of a custom chassis subcategory identifier will instruct GEM to simulate the vehicle using an EPA default engine.

⁴³³ See Section II.D.5 for an explanation of which engine architecture will need to meet which standard.

⁴³⁴ As noted in Section II.B.2 above, manufacturers also have greater flexibility to meet a vehicle standard if engine improvements can be evaluated as part of compliance testing.

(c) Technologies the Agencies Assessed But Did Not Use In Standard-Setting

(i) Aerodynamics

The agencies did not propose to include aerodynamic improvements as a basis for the Phase 2 vocational vehicle standards. However, we did request comment on an option to allow credits for use of aerodynamic devices such as fairings on a very limited basis. We received public comments from AAPC in support of offering this as an optional credit, with a suggestion to allow this option for a wide range of vehicle sizes, and suggesting that the grams per ton-mile benefit could be scaled down for larger vehicles. CARB commented in support of a Phase 2 program that would include use of aerodynamic improvements as a basis for the stringency, suggesting that a large fraction of the vocational vehicle fleet could see real world benefits from use of aerodynamic devices. Because we do not have sufficient fleet information to establish a projected application rate for this technology, we are not basing any of the final standards for vocational vehicles on use of aerodynamic improvements. See 80 FR 40303. In consideration of comments, however, we are adopting provisions for vocational vehicles to optionally receive an improved GEM result by certifying use of a pre-approved aerodynamic device, and are expanding eligibility criteria from the relatively narrow criteria proposed.

Based on testing supported by CARB, the agencies have developed a list of specific aerodynamic devices with pre-defined improvement values (in delta $C_D A$ units), as well as criteria regarding which vehicles are eligible to earn credit in this manner. See Chapter 2.9.4.1 of the RIA. In response to comments, we are allowing a wide range of vehicles to be eligible to use this option. Regional vocational vehicles in any weight class may use this option, subject to restrictions on the size of the chassis (see 40 CFR 1037.520). The degree of change in $C_D A$ for each pre-approved device has been set at conservative values due to the small number of configurations tested and the uncertainty inherent in those results. Manufacturers wishing to receive credit for other aerodynamic technologies or on other vehicle configurations may seek credit using the test procedures described in 40 CFR 1037.527. Manufacturers using this credit provision may enter the pre-defined delta $C_D A$ as an input to GEM, and the simulation will determine the effectiveness over the duty cycle. Using this approach, we do not need to set a

scaled benefit for different sizes of vehicles. When the vehicle weight class and duty cycle is specified, a default chassis mass and payload are simulated in GEM. When the pre-defined delta $C_D A$ is entered, the simulation returns a resulting improved performance with respect to the specified chassis configuration. GEM will logically return a smaller improvement for heavier vehicles.

The final Regional composite duty cycle in GEM for vocational vehicles has a weighted average speed of 38 mph, increased from the average speed at proposal due to a heavier 56 percent composite weighting of the 65 mph drive cycle. The agencies have learned from the NREL duty cycle analysis that vocational vehicles with operational behavior of a regional nature accumulate more miles at highway speeds than previously assumed.

Using GEM simulation results, the agencies estimate the fuel efficiency benefit of improving the $C_D A$ of a Class 6 box truck by 11 percent (0.6 m^2 delta $C_D A$ off of a default of 5.4 m^2) at approximately five percent over the Regional composite test cycle. This same delta $C_D A$ simulated in GEM on a class 8 Regional vocational vehicle results in an overall improvement of less than four percent because the default $C_D A$ in GEM for class 8 vocational vehicles is 6.86 m^2 so the change in $C_D A$ is only nine percent. Although in actual operation the added weight of aerodynamic fairings may reduce the operational benefits of these technologies when driving at low speeds, the agencies are not applying any weight penalty as part of the certification process for vocational aerodynamic devices.

As described in the NPRM, we are requiring chassis manufacturers employing this option to provide assurances to the agencies that these devices will be installed as part of the certified configuration, even if the installation is completed by another entity. We received many comments on the requirements for secondary manufacturers as they apply for vocational aerodynamics as well as other technologies that may be specified by a chassis manufacturer but installed later. See Section I.F.2 and Section V.D.2 for further discussion of delegated assembly issues.

(ii) Full Electric Trucks

Given the high up-front costs and the developing nature of this technology, the agencies do not project fully electric vocational vehicles to be widely commercially available in the time frame of the final rules. For this reason,

the agencies have not based the Phase 2 standards on adoption of full-electric vocational vehicles. We received many comments on electric trucks and buses. Specifically, EEI provided information on the total cost of ownership for electric trucks, and some applications may see attractive long term cost scenarios for electric trucks or buses, when considering maintenance savings. While we are not predicated the final vocational vehicle standards on adoption of full electric trucks or buses, we have reinstated an advanced technology credit multiplier, in response to comment. See Section I.C.1.(b) for a discussion of credit multipliers.

To the extent this technology is able to be brought to market in the time frame of the Phase 2 program, there is currently a certification path for these chassis from Phase 1, as described in EPA's regulations at 40 CFR 1037.150 and NHTSA's regulations at 49 CFR 535.8.

(iii) E-PTO

Although the primary program does not simulate vocational vehicles over a test cycle that includes PTO operation, the agencies are adopting a revised hybrid-PTO test procedure. See 76 FR 57247 and 40 CFR 1037.540. Recall that we regulate vocational vehicles at the incomplete stage when a chassis manufacturer may not know at the time of certification whether a PTO will be installed or how the vehicle will be used. Chassis manufacturers may rarely know whether the PTO-enabled vehicle will use this capability to maneuver a lift gate on a delivery vehicle, to operate a utility boom, or merely to keep it as a reserve item to add value in the secondary market. For these reasons, it would not be fair to require every vocational vehicle to certify to a standard test procedure with a PTO cycle in it. Thus, we are not basing the final standards on use of technology that reduces emissions in PTO mode.

There are products available today that can provide auxiliary power, usually electric, to a vehicle that needs to work in PTO mode for an extended time, to avoid idling the main engine. There are different designs of electrified PTO systems on the market today. Some designs have auxiliary power sources, typically batteries, with sufficient energy storage to power an onboard tool or device for a short period of time, and are intended to be recharged during the workday by operating the main engine, either while driving between work sites, or by idling the engine until a sufficient state of charge is reached that the engine may shut off. Other designs have

sufficient energy storage to power an onboard tool or device for many hours, and are intended to be recharged as a plug-in hybrid at a home garage. In cases where a manufacturer can certify that a PTO with an idle-reduction technology will be installed either by the chassis manufacturer or by a second stage manufacturer, the hybrid-PTO test cycle may be utilized by the certifying manufacturer to measure an improvement factor over the GEM duty cycle that otherwise applies to that vehicle. In addition, the delegated assembly provisions will apply (see Section V.D). See RIA Chapter 3.7.4 for a discussion of the revisions to the PTO test cycle.

The agencies will continue the hybrid-PTO test option that was available in Phase 1, with a few revisions. See the regulations at 40 CFR 1037.540. The calculations recognize fuel savings over a portion of the test that is determined to be charge-sustaining as well as a portion that is determined to be charge-depleting for systems that are designed to power a work truck during the day and return to the garage where recharging from an external source occurs during off-hours. The agencies requested comment on this idea, and received comment from Odyne relating to the population and energy storage capacity of plug-in e-PTO systems, for which a charge-depleting test cycle may be more appropriate. We also partnered with DOE-NREL to characterize the PTO operation of over 80 trucks with over 1,500 total operating days, and our final regulations include a utility factor table based on these data for use in determining the effectiveness of a hybrid PTO system.⁴³⁵ Manufacturers wishing to conduct testing as specified may apply for off-cycle credits derived from e-PTO or hybrid PTO technologies.

(2) Projected Vehicle Technology Package Effectiveness and Cost

(a) Baseline Vocational Engine and Vehicle Performance

The baseline vocational vehicle configurations for each of the nine regulatory subcategories for CI-powered and six SI-powered vehicles are described in RIA Chapter 2.9.1, as well as the seven baseline custom chassis configurations. The agencies set the baseline rolling resistance coefficient for the 2017 vocational vehicle fleet at 7.7 kg/metric ton, which assumes that 100 percent of tires meet the Phase 1 standard.

In the agencies' Phase 2 baseline configurations, we need to specify transmission type, gear number, and gear ratios, as well as axle ratios and tire sizes because these were all defaults in Phase 1. Phase 1 GEM modeled all vehicles with a manual transmission, but as explained elsewhere, the majority of vocational vehicles in today's U.S. fleet have automatic transmissions. By specifying a mix of manual and automatic transmissions with different sets of gears in the baseline, we are not applying technology beyond what is needed to comply with Phase 1, we are merely defining an appropriate set of baselines. We do not consider these specifications to represent technology that improves fuel efficiency beyond Phase 1, it is merely a better representation of today's fleet than the Phase 1 GEM that had 100 percent default manual transmissions. In the Regional HHD diesel subcategory, the baseline is a weighted average of two vehicle specs: 95 percent being a 455 hp engine paired with a manual transmission with ten forward gears, and five percent being a 350 hp engine paired with a 6-speed automatic transmission. The HHD Multipurpose subcategory is a weighted average of three vehicle specs: 80 percent being a 350 hp engine paired with a 6-speed automatic transmission, 10 percent being a 455 hp engine paired with a 10-speed manual transmission, and 10 percent being a 350 hp engine paired with a 10-speed manual. The automatic transmissions specified in the LHD, MHD, and HHD Regional and Multipurpose subcategories have six forward gears in the baseline, while automatic transmissions in the Urban subcategories have five forward gears in the baseline. This is based on market research, stakeholder outreach, and comments received on the NODA. No vehicle-level efficiency-improving technology is included in the baseline vehicles, nor in the agencies' analyses for the no-action reference case. Specifically, we have assumed zero adoption rates for other types of transmissions, other numbers of gears, idle reduction, and technologies other than Phase 1 compliant LRR tires in both the nominally flat baseline and the dynamic baseline reference cases. Technology adoption rates for Alternative 1a (nominally flat baseline) can be found in the RIA Chapter 2.11. Chapter 2.11.8 presents the adoption rates for tires on vocational vehicles with different levels of rolling resistance, including the 100 percent

adoption rate of tires with Level 1 CRR in the reference case and in model years preceding Phase 2. In this manner, we have defined a reference vocational vehicle fleet that meets the Phase 1 standards and includes reasonable representations of vocational vehicle technology and configurations.

The agencies note that the baseline performance derived for the final rules varies between regulatory subcategories—as noted above, this is one of the reasons the agencies are adopting multiple subcategories with discrete standards. The range of performance at baseline is due to the range of attributes and modeling parameters, such as transmission characteristics, final drive ratio, and vehicle weight, which were selected to represent a range of performance across this diverse segment. The agencies received persuasive comment regarding the appropriateness of the baseline configurations, and have made revisions accordingly. For example, we have reduced the LHD default aerodynamic drag area from 5.4 to 3.4 square meters. We are confident these adequately represent a reasonable range of vocational chassis configurations currently manufactured in the US. Details of the vehicle configurations, including reasons why they are reasonably included as baseline technologies, are discussed in the RIA Chapter 2.9.2.

At proposal the agencies adjusted the vocational vehicle GEM numerical baselines using assumptions about the sales mix in the vocational fleet before applying the reductions from technologies. 80 FR 40308. In this process, we developed proposed baseline values that we believed would minimize inappropriate incentives for manufacturers to certify chassis in an inappropriate subcategory. The proposed approach included testing each baseline vehicle over all three duty cycles and applying weighted average adjustments to each GEM output to create normalized baselines, 80 FR 40308. We received adverse comment on this approach from many commenters—indeed, no commenter supported this “normalization” approach. The proposed normalization approach was an attempt to adjust for instances where the agencies' information on baseline configurations was not fully complete. Most commenters either opposed or were confused by the proposed normalization process. As explained in this Section V., the agencies are adopting final standards for vocational vehicles using the same methodology as for all the other standards in this rulemaking, and

⁴³⁵ National Renewable Energy Laboratory July 2016, “Characterization of PTO and Idle Behavior for Utility Vehicles,” NREL/TP-5400-66747.

so are neither normalizing nor equalizing any of the data relating to either the baseline or the standard. (Equalization is discussed separately in Section V.C.(2)(d) below.) The agencies have received a great deal of information from manufacturers since proposal which rectify weaknesses in our baselines, and make any normalization unnecessary.⁴³⁶ In the final rules we have applied other methods (chiefly certain equipment-based constraints) to avoid creating inappropriate incentives for manufacturers to certify chassis in inappropriate subcategories. The final standards are calculated by applying improvements as described below in

Section V.C.(2)(c) to the GEM results presented in Table V–17 and Table V–18—the same methodology as used to develop the other Phase 2 standards.

Diesel engines used in vocational vehicles can be either Light, Medium, or Heavy Heavy-duty Diesel engines. The Light Heavy-duty Diesel engines typically range between 4.7 and 6.7 liters displacement. The Medium Heavy-duty Diesel engines typically have some overlap in displacement with the Light Heavy-duty Diesel engines and range between 6.7 and 9.3 liters. The Heavy Heavy-duty Diesel engines typically are represented by engines between 10.8 and 16 liters. Because of these differences, the GEM simulation of

baseline vocational CI engines includes four engines—one for LHD, one for MHD, and two for HHD. Detailed descriptions can be seen in Chapter 4 of the RIA. These four engine models have been employed in setting the vocational vehicle baselines, as described in the RIA Chapter 2.9.1.

The four baseline diesel engines represent fuel consumption improvements beyond currently available engines to achieve the performance level of a 2017 model year diesel engine, as described in the RIA Chapter 2.9.1. Using the values for compression-ignition engines, the baseline performance of vocational vehicles is shown in Table V–17.

TABLE V–17—BASELINE VOCATIONAL VEHICLE PERFORMANCE WITH CI ENGINES

Duty cycle	Light heavy-duty Class 2b–5	Medium heavy-duty Class 6–7	Heavy heavy-duty Class 8
Baseline Emissions Performance in CO₂ gram/ton-mile			
Urban	482	332	338
Multi-Purpose	420	294	287
Regional	334	249	220
Baseline Fuel Efficiency Performance in gallon per 1,000 ton-mile			
Urban	47.3477	32.6130	33.2024
Multi-Purpose	41.2574	28.8802	28.1925
Regional	32.8094	24.4597	21.6110

The agencies have developed a model in GEM of a MY 2016-compliant gasoline engine. The agencies received comments on the process for mapping gasoline engines for simulation purposes, as well as information about the power rating and displacement that should be considered as a baseline SI engine for vocational vehicle standard-setting purposes. Upon consideration of comments, and based on information obtained through testing at Southwest Research (see Chapter 5.5 of the SwRI report), we are adopting revised test procedures as described in the RIA Chapter 3.1 that apply for mapping of both SI and CI engines.⁴³⁷

The baseline performance levels for vocational vehicles powered by SI engines were derived using the EPA default fuel map described in the RIA Chapter 2.9.1, for a 6.8 liter, V–8, 300 hp engine. We have used the same

engine rating and map for all weight classes of SI vocational vehicles. This is because SI engines are not certified with a regulatory structure that calls for declaring an intended service class that is associated with a vehicle weight class. The agencies requested comments on the merits of setting distinct numerical standards for HHD vocational vehicles powered by SI engines, as well as comments on an alternative approach that would have required any class 8 SI vocational vehicles to certify to the standards for CI powered HHD vocational vehicles, or to the MHD standards for SI vocational vehicles. In response to comments expressing concern about orphaned vehicles as well as concerns about mismatched engine and vehicle useful life, the agencies are not finalizing distinct HHD SI vocational vehicle standards. We are finalizing six subcategories for SI

vocational vehicles: Three LHD and three MHD. Where a manufacturer wishes to certify a gasoline SI vocational vehicle with a GVWR over 33,000 lbs, the final regulations allow that vehicle to be certified in one of the MHD vehicle subcategories. Where a manufacturer wishes to certify an alternative-fueled vocational vehicle with a GVWR over 33,000 lbs, the regulations at 40 CFR 1036.108 specify whether that vehicle should be treated as SI or CI for purposes of certification to the final Phase 2 standards. See Section II.D.5 of this Preamble for a discussion of these provisions.

Table V–18 presents the baseline performance level for each weight class computed by GEM by calculating the work done by the default engine to move the GEM reference vehicles over the test cycles.

⁴³⁶ See memorandum dated July 2016 titled, “Summary of Comments on Vocational Vehicle Baselines,” see Docket EPA–HQ–OAR–2014–0827.

⁴³⁷ Michael Ross, *Validation Testing for Phase 2 Greenhouse Gas Test Procedures and the Greenhouse Gas Emission Model (GEM) for Medium*

and Heavy-Duty Engines and Powertrains, Final Report to EPA, Southwest Research Institute, June 2016.

TABLE V-18—BASELINE VOCATIONAL VEHICLE PERFORMANCE WITH SI ENGINES

Duty cycle	Light heavy-duty Class 2b-5	Medium heavy-duty Class 6-7 (and Gasoline c8) ^a
Baseline Emissions Performance in CO₂ gram/ton-mile		
Urban	502	354
Multi-Purpose	441	314
Regional	357	275
Baseline Fuel Efficiency Performance in gallon per 1,000 ton-mile		
Urban	56.4870	39.8335
Multi-Purpose	49.6230	35.3325
Regional	40.1710	30.9441

Note:

^a Vocational vehicles with GVWR over 33,000 lbs powered by alternate fueled engines must certify to the vehicle standard corresponding with the applicable engine standard.

(b) Technology Packages for Derivation of Final Standards

Prior to developing the numerical values for the final standards, the agencies projected the mix of new technologies and technology improvements that will be feasible within the available lead time. We note that for some technologies, the adoption rates and effectiveness may be very similar across subcategories. However, for other technologies, either the adoption rate, effectiveness, or both differ across subcategories. Where a technology performs differently over different test cycles, these differences are reflected in the derivation of the stringency of the standard. As discussed in Section I.C.1, we assume manufacturers will incorporate appropriate compliance margins for all measured GEM inputs. In other words, they will declare values slightly higher than their measured values. As discussed in Section II.D.5, compliance margins associated with fuel maps are likely to be approximately one percent. For tire rolling resistance, our feasibility rests on the Phase 1 standards, consistent with our expectation that manufacturers will continue to incorporate the compliance margins they considered necessary for Phase 1. With respect to optional axle and/or transmission power loss maps, we believe manufacturers will need very small compliance margins. These power loss procedures require high precision so measurement uncertainty will likely be on the order of 0.1 percent of the transmitted power. All of these margins are reflected in our projections of the emission levels that will be technologically feasible, as well as the associated costs.

In the package descriptions that follow, individual technology costs are

not presented, rather these can be found in the RIA Chapter 2.9 and 2.11. Section V.C.(2)(d) includes the costs estimated for packages of technologies the agencies project can be applied to vocational vehicles to meet the final Phase 2 standards.

(i) Transmission Packages

The agencies project an adoption rate of 50 percent in MY 2021, 60 percent in MY 2024, and nearly 70 percent in MY 2027 of transmissions with improved gear efficiencies, with inputs over-riding the GEM defaults obtained over the separate transmission efficiency test. We are projecting an adoption rate of 10 percent in MY 2021, 20 percent in MY 2024, and nearly 30 percent in MY 2027 of advanced shift strategies, with demonstration of improvements recognized over the separate powertrain test.

We are predicating the Phase 2 standards on zero adoption of added gears in the HHD Regional subcategory, because it is modeled with a 10-speed transmission, and vehicles already using that number of gears are not expected to see any real world improvement by increasing the number of available gears. For the Multipurpose and Urban HHD subcategories, the MY 2021 projected adoption of adding gears is 5 percent, increasing to 10 percent for MY 2024 and MY 2027. We are projecting 10 percent of adding two gears in each of the other six subcategories for MY 2021, increasing to 20 percent for MY 2024 and MY 2027. Commenters supported the inclusion of this technology as part of the basis for the standards. Allison commented that they have configured an 8-speed vocational transmission. Eaton's new MHD dual clutch transmission has seven forward gears. There is also a likelihood that suppliers of 8-speed transmissions for HD pickups

and vans may sell some into the LHD vocational vehicle market.

We are also predicating the optional custom chassis standards for school and coach buses in part on adoption of transmissions with additional gears. In MY 2021, this adoption rate is five percent, increasing to 10 percent in MY 2024 and 15 percent in MY 2027. Manufacturers who certify these vehicles to the primary standards will use GEM to model the actual gears and gear ratios; however, manufacturers using custom chassis regulatory subcategory identifiers will not have this flexibility. The agencies have estimated the cycle-average benefit of adding an extra gear for school buses (modeled as MHD Urban vehicles) at 0.9 percent and coach buses (with 6 gears in the baseline) at 1.7 percent; therefore, manufacturers using custom chassis regulatory subcategory identifiers for these vehicles will be permitted to enter these pre-defined improvement values at the time of certification.

Based on comment regarding our regulatory baselines, both the HHD Regional and HHD Multipurpose subcategories now have manual transmissions in the baseline configuration. For these vehicles, the agencies project upgrades to automated transmissions such as either AMT, DCT, or automatic, at an adoption rate of 30 percent in MY 2021, 50 percent in MY 2024, and 80 percent in MY 2027 for Regional vehicles. For Multipurpose, beginning with 20 percent manuals in the baseline, the adoption rate of automated transmissions is five percent in MY 2021 and 20 percent in MY 2024. Consistent with our projections of technology adoption, the regulations require that any vocational vehicles with manual transmissions must be certified as Regional in MY 2024 and beyond. This progression of

transmission automation is consistent with the agencies' projection of 10 percent manuals and 90 percent automated transmissions in the day cab tractor subcategories in MY 2027. See Table III–13. HHD vocational vehicles in regional service have many things in common with day cab tractors, including the same assumed engine size and typical transmission type, and a similar duty cycle. Thus, it is reasonable for the agencies to make similar projections about the fraction of automated vs manual transmissions adopted over the next decade among these sectors. Also consistent with tractors, GEM simulates each of these with a two percent fixed effectiveness improvement over the performance of the MT in the baseline. To the extent any of these transmissions provide additional effectiveness over the GEM cycles with actual OEM data entered, it is not considered in the stringency of the vocational vehicle HHD Regional standard (but would be recognized at certification). The agencies have been unable to characterize the relative effectiveness of DCT compared with AT sufficiently to apply it as a technology on which stringency is predicated. This is consistent with the public comment on this issue: Daimler did not support inclusion of DCT as a technology with different effectiveness than AMT, and Allison did not support treatment of either DCT or AMT as different as AT.

In the seven subcategories (*i.e.* all of the remaining subcategories) in which automatic transmissions are the base technology, the agencies project that ten percent of the HHD vehicles will apply an aggressive torque converter lockup strategy in MY 2021, and 30 percent in the LHD and MHD subcategories. These adoption rates are projected to increase to 20 percent for HHD and 40 percent for LHD and MHD in MY 2024. We project adoption of aggressive torque converter lockup for HHD automatics of 30 percent in MY 2027, and 50 percent for LHD and MHD.

In setting the standard stringency, we have projected that non-integrated (bolt-on) mild hybrids will not have the function to turn off the engine at stop, while the integrated mild hybrids will have this function. The agencies have estimated the effectiveness for vehicles certified in the Urban subcategories will achieve as much as 13 percent improvement, and integrated systems that turn off at stop will see up to 21 percent improvement depending on the subcategory. We have also projected zero hybrid adoption rate (mild or otherwise) by vehicles in the Regional subcategories, expecting that the benefit of hybrids for those vehicles will be too

low to merit use of that type of technology. However, there is no fixed hybrid value assigned in GEM and, for any vehicles utilizing hybrid technology, the actual improvement over the applicable test cycle will be determined by powertrain testing, which would likely reflect some benefit of hybrids on Regional vehicles. By the full implementation year of MY 2027, the agencies are projecting an overall vocational vehicle adoption rate of 12 percent mild hybrids, which we estimate will be 14 percent of vehicles certified in the Multi-Purpose and Urban subcategories (six percent integrated and eight percent non-integrated). We are projecting a low adoption rate in the early years of the Phase 2 program, zero integrated hybrid systems and two percent of the bolt-on systems in these subcategories in MY 2021, and three percent integrated mild hybrids in MY 2024 for vehicles certified in the Multi-Purpose and Urban subcategories, plus 5 percent non-integrated mild hybrids in MY 2024. Based on our assumptions about the populations of vehicles in different subcategories, these hybrid adoption rates are about two percent overall in MY 2021 and six percent overall in MY 2024.

Navistar commented with concerns that the agencies may be double counting some of the improvements of deep integration. For example, the addition of a gear to a transmission may reduce the added benefit of deep integration, as the transmission may already achieve a more optimal operation state more often due to the greater number of gears. The agencies have been careful to project adoption rates and effectiveness of transmission technologies in a way that that avoids over-estimating the achievable reductions. For example, as we developed the packages, we reduced the adoption rate of advanced shift strategy by the adoption rate of integrated hybrids, and we reduced the adoption rate of transmission gear efficiency by the amount of non-integrated hybrids. This is because we do not project that any driveline will undergo testing over both the powertrain test and the separate transmission efficiency test. Because we have projected adoption of combinations of transmission technologies in some subcategories, the sum of adoption rates of individual transmission technologies may exceed 100 percent in some cases. However, the effectiveness values have not been summed because we agree with the commenter that we should not double count benefits. Instead of summing the

combined efficiencies, we combine multiplicatively as described in Equation V–1, below. Thus, we have fairly accounted for dis-synergies of effectiveness where multiple technologies are applied to a similar vehicle system.

Custom chassis manufacturers have provided compelling comment that the absence of recognition in the certification process of improved transmission technology will not deter them from its adoption. Therefore, although some types of improved transmissions are feasible for some custom chassis, these vehicles are typically assembled from off-the-shelf parts in low production volumes. For most components, this is not a significant obstacle. However, this dynamic can limit their access to the most advanced transmission technologies. Transmission manufacturers would generally be willing to supply advanced transmissions they developed for a larger customer, but would be less likely to invest in developing a special low volume transmission for the custom chassis. Similar circumstances would apply for hybrids. Further, for the reasons described above about non-representative drivelines in the baseline configurations, we believe that allowing these to be certified with a default driveline is a reasonable program structure. For school buses and others, if a manufacturer wishes to be recognized beyond the levels described for adopting improved transmissions, it has the option of certifying to the primary standards. Nevertheless, technology improvements that some of these manufacturers will include based on market forces (after they have been introduced into the market as a result of the primary program) will likely result in actual in-use improvements for many these vehicles beyond what is projected by the standards.

(ii) Axle Packages

The agencies project that 10 percent of vocational vehicles in all subcategories will adopt high efficiency axles in MY 2021, 20 percent in MY 2024, and 30 percent in MY 2027. Fuel efficient lubricant formulations are widespread across the heavy-duty market, though advanced synthetic formulations are currently less popular.⁴³⁸ Axle lubricants with improved viscosity and efficiency-enhancing performance are projected to

⁴³⁸ See meeting log for proposed rule, specifically the April 2014 meeting with Dana. <https://www.regulations.gov/document?D=EPA-HQ-OAR-2014-0827-0702>

be widely adopted by manufacturers in the time frame of Phase 2. Such formulations are commercially available and the agencies see no reason why they could not be feasible for most vehicles. Nonetheless, we have refrained from projecting full adoption of this technology. The agencies do not have specific information regarding reasons why axle manufacturers may specify a specific type of lubricant over another, and whether advanced lubricant formulations may not be recommended in all cases. The agencies received adverse comment on allowing fixed credit for use of high efficiency axles, whether from lubrication or other mechanical designs. In response, we are adopting a separate axle efficiency test, which can be used as an input to GEM to over-ride default axle efficiency values. The low overall adoption rate indicates that we expect axle suppliers to only offer high-efficiency axles for their most high production volume products, especially those that can serve both the tractor and vocational market. Therefore, we believe it is unlikely that high-efficiency axles will be adopted in custom chassis applications. Because we are no longer offering a fixed improvement for this technology as at proposal, this is only available for vocational vehicles that are certified to the primary program.

The agencies estimate that 10 percent of HHD Regional vocational vehicles and five percent of HHD Multipurpose vehicles will adopt part time 6x2 axle

technology in MY 2021. This technology is most likely to be applied to Class 8 vocational vehicles (with 2 rear axles) that are designed for frequent highway trips. The agencies project a 20 percent adoption rate for HHD Regional and 15 percent adoption rate for HHD Multipurpose for part time 6x2 axle technologies in MY 2024. In MY 2027, we project 30 percent adoption of part time 6x2 for HHD Regional and 25 percent for HHD Multipurpose. We are establishing a custom chassis baseline configuration for coach buses with a 6x2 axle, in consideration of comments from UCS and manufacturers stating this is the standard axle configuration for these vehicles. If a HHD coach bus is sold with a 6x4 or part time 6x2 axle, the manufacturer must enter the as-built axle configuration as a GEM input. This is true whether the vehicle is in the primary program or if it is certified to the custom chassis standard. Because the optional custom chassis standard assumes a 6x2 axle in the coach bus baseline, manufacturers may only qualify to obtain a reduced GEM result from use of the 300 pound weight reduction value (specified in 40 CFR 1037.520 associated with use of a permanent 6x2 axle) when certifying coach buses to the primary standards.

(iii) Tire Packages

The agencies estimate that the per-vehicle average level of rolling resistance from vocational vehicle tires could be reduced by up to 13 percent for many vehicles by full implementation of

the Phase 2 program in MY 2027, based on broader adoption of vocational vehicle tires currently available. We estimate this will yield reductions in fuel use and CO₂ emissions of up to 3.3 percent for these vehicles. All of our estimates of vehicle-level tire CRR improvements employ a weighted average using an assumed axle load distribution of 30 percent on the steer tires and 70 percent on the drive tires, as was proposed.⁴³⁹ The projected adoption rates of tires with improved CRR for chassis in the primary program are presented in Table V–19. The levels noted in the table are defined above in Table V–15. By applying the assumed axle load distribution, the estimated vehicle CRR improvement projected as part of the MY 2021 standards ranges from 5 to 8 percent, which we project will achieve up to 1.9 percent reduction in fuel use and CO₂ emissions, depending on the vehicle subcategory. The agencies estimate the vehicle CRR improvement in MY 2024 will range from 5 to 13 percent, yielding reductions in fuel use and CO₂ emissions up to 3.2 percent, depending on the vehicle subcategory.

The agencies believe that these tire packages recognize the variety of tire purposes and performance levels in the vocational vehicle market, and maintain choices for manufacturers to use the most efficient tires (*i.e.* those with lowest rolling resistance) only where it makes sense given these vehicles' differing purposes and applications.

Table V–20 presents the projected adoption rates of LRR tires for custom chassis. As noted above in Section V.C.(1)(a)(iii), the adoption rates generally represent improvements in the range of the 25th to 40th percentile using data from actual vehicles in each application that were certified in MY

2014. A summary of these data is provided in a memorandum to the docket.⁴⁴⁰ An exception to this is emergency vehicles. The final emergency vehicle standards reflect adoption of tires that progress to the 50th percentile by MY 2027, using steer and drive tire data for certified

emergency vehicles. At these adoption rates, manufacturers need not change any of the tires they are currently fitting on emergency vehicles, and they will comply on average.

⁴³⁹ See Vehicle Valuation Services Quick Reference Guide, available at <http://www.vvsi.com/training/TrainingGuide.pdf>, (accessed June 2014),

the draft RIA at Chapter 2.9.2, and Docket ID EPA–HQ–OAR–2014–0827–0434.

⁴⁴⁰ See memorandum on tire data, Note 419, above.

TABLE V–20—PROJECTED LRR TIRE ADOPTION RATES FOR CUSTOM CHASSIS

(iv) Idle Reduction Packages

In these rules, the adoption rate of AES for HHD Regional vehicles is 40 percent in MY 2021, 80 percent in MY 2024, and 90 percent in MY 2027. This is because these vehicles have driving patterns with a significant amount of parked idle, and the vast majority have relatively modest accessory demands such that only a few would have such large demands for backup power that turning the engine off while parked

would not be feasible. For all weight classes of Regional vehicles except coach buses, the neutral idle and stop start adoption rates remain zero in all model years because these vehicles have driving patterns with such a small amount of transient driving that this drive-idle technology would not likely provide real world benefits. For coach buses we are predicating the optional custom chassis standard in part on adoption of neutral idle for several reasons. First, according to Volvo, we are underestimating the amount of transient time for these vehicles by applying only a 20 percent weighting of the transient cycle instead of 25 percent as noted in their comment. Second, we estimate that neutral idle is a low cost technology that would easily pay for itself with the miles accumulated by coach buses. Finally, in the custom chassis program manufacturers are able to qualify for a reduced emission rate in GEM through selection of neutral idle even if the transmission architecture inherently functions with neutral idle such as with an AMT or DCT. The Regional vehicles carry a 40 percent, 80 percent, and 90 percent adoption rate of AES in MYs 2021, 2024, and 2027 respectively because these vehicles are not projected to apply any other idle reduction technology and as long as large accessory loads are not required this technology is widely feasible. As reflected in the Multipurpose and Urban

duty cycles with an overall composite test weighting of zero speed operation of 50 percent with 25 percent composite weighting of the parked idle cycle, idle reduction is a significant technology for these vehicles. We are projecting 30 percent adoption of AES in all weight classes of Multipurpose and Urban vocational vehicles in MY 2021, increasing to 60 percent in MY 2024 and 70% in MY 2027. This is less than for Regional because we expect a larger fraction of vehicles in these subcategories will need to run PTO or other accessories while parked, such that fewer will be able to reasonably apply the low-cost AES that we have identified in this rulemaking. Because we are considering stop-start and neutral idle to be mutually exclusive on a per-vehicle basis, the sum of these two technologies does not exceed 90 percent in MY 2027, and gradually ramps up to this level from the 50 to 60 percent range in MY 2021. Neutral idle adoption rates are greater in the early years because we expect this will not need much lead time, if any. An exception to the 90 percent maximum adoption rate is transit buses, where we believe all vehicles of this type can reasonably apply some form of drive idle reduction technology. The adoption rates of idle reduction technologies for vocational vehicles in MY 2027 is presented in Table V–21.

TABLE V–21—MY 2027 ADOPTION RATES OF IDLE REDUCTION TECHNOLOGIES

Technology	Heavy heavy-duty			Medium heavy-duty			Light heavy-duty		
	Regional	Multi-purpose	Urban	Regional	Multi-purpose	Urban	Regional	Multi-purpose	Urban
Neutral Idle	0	70	70	0	60	60	0	60	60
Stop-Start	0	20	20	0	30	30	0	30	30
AES	90	70	70	90	70	70	90	70	70

Although it is possible that a vehicle could have both neutral idle and stop-start, our stringency calculations only consider emissions reductions where a vehicle either has one or the other of these technologies. The final GEM input file allows users to apply multiple idle reduction technologies within a single vehicle configuration.

Because we have included costs to maintain engine protection during periods of shut-off, as well as over-rides to recognize instances where it may not be safe to shut off an engine, we believe stop-start can safely be applied at the rates described above in the time frames described. Also, because we have defined two idle cycles where the

automatic engine shutoff technology addresses the condition of being parked with the brake off, we believe this alleviates many of the concerns expressed by commenters about stop-start. We believe many commenters were (erroneously) imagining that stop-start systems would be required to function during periods of extended parking.

We agree with commenters that stop-start is not feasible for emergency vehicles and concrete mixers. We further believe that stop-start would not provide any real world benefit for coach buses or motor homes. However, for school buses, transit buses, and refuse trucks, we believe stop-start is feasible

and likely to result in real world benefits. The only custom chassis standards that we are basing on adoption of AES is school buses, because for the others, we believe the simple shutdown timer would be likely to encounter an over-ride condition frequently enough to yield a very small benefit from this technology. To make AES practical for a coach or transit bus for example, a much larger auxiliary power source would be needed than the one projected as part of this rulemaking. Although many school buses have voluntarily adopted idle reduction strategies for other reasons, we do not believe many have tamper-proof automatic shutdown systems.

TABLE V-22—CUSTOM CHASSIS WORKDAY IDLE ADOPTION RATES

Technology	MY	AES	NI	Stop-start
Coach	2021		40	
	2027		70	
School	2021	30	60	5
	2027	70	60	30
Transit	2021		60	10
	2027		70	30
Refuse	2021		30	0
	2027		50	20

As described above, the agencies are excluding refuse trucks that do not compact waste from the optional custom chassis vocational vehicle standards. We believe trucks that do not compact waste have sufficiently low PTO operation (usually only while parked) to make application of drive idle reduction technologies (and other technologies projected for regular vocational chassis) quite feasible. Front-loading refuse collection vehicles tend to have a relatively low number of stops per day as they tend to collect waste from central locations such as commercial buildings and apartment complexes. Because these have a relatively low amount of PTO operation, we expect stop-start will be reasonably effective for these vehicles. Rear-loading and side-loading neighborhood waste and recycling collection trucks are the refuse trucks where the largest number of stop-start and neutral idle over-ride conditions are likely to be encountered. Because chassis manufacturers, even those with small production volumes and close customer relationships, do not always know whether a refuse truck chassis will be fitted with a body designed for front loading, rear loading, or side loading, we are applying an adoption rate of 20 percent stop-start in 2027 to refuse trucks certified as custom chassis. In the case where a chassis manufacturer certifies a refuse truck to the primary standards under the HHD Urban subcategory, the MY 2027 adoption rate of stop-start is also 20 percent as shown in Table V-21. The stringency in both cases assumes a sufficiently capable stop-start system to not require an excessive use of over-rides. Manufacturers opting to certify refuse trucks to the primary standards will have an option to be recognized for enhanced stop-start systems through the powertrain test.

It may take some minor development effort to apply neutral idle to high-torque automatic transmissions designed for the largest vocational vehicles. Based on stakeholder input, the designs needed to avoid an uncomfortable re-engagement bump

when returning to drive from neutral may require some engineering refinement as well as some work to enable two-way communication between engines and transmissions. Nonetheless, this technology should be available in the near term for many vehicles and is low cost compared to many other technologies we considered. Commenters asked for over-rides such as when on a steep hill and we agree and are adopting this provision.

For the reasons described above, we see the above idle reduction technologies being technically feasible on the majority of vocational vehicles. The RIA Chapter 2.9.3.4 and RIA Chapter 2.9.5.1.4 provide additional discussion on workday idle reduction technologies for vocational vehicles.

(v) Weight Reduction Packages

As described in the RIA Chapter 2.11.10.3, weight reduction is a relatively costly technology, at approximately \$3 to \$10 per pound for a 200-lb package. Even so, for vehicles in service classes where dense, heavy loads are frequently carried, weight reduction can translate directly to additional payload. The agencies project that modest weight reduction is feasible for all vocational vehicles. The agencies are predicated the final standards on adoption of weight reduction comparable to what can be achieved through use of aluminum wheels (an easy material switch that does not alter load distribution on the chassis). This package is estimated at 150 pounds for LHD and MHD vehicles, and 250 pounds for HHD vehicles, based on six and 10 wheels, respectively. This value is revised upward since proposal based on compelling comments from the Aluminum Association recommending that we set the same level of weight reduction for lightweight aluminum alloys as for regular aluminum, at 25 pounds per wheel. More details on these comments may be found in the Response to Comments Chapter 5. In MY 2021, we project an adoption rate of 10 percent, 30 percent in MY 2024, and

50 percent in MY 2027 for all subcategories in the primary program.

The agencies project manufacturers will have sufficient options of other components eligible for material substitution so that this level of weight reduction will be feasible even where aluminum wheels are not selected by customers. Based on comments, we have removed aluminum transmission cases and aluminum clutch housings from the vocational lookup table.

We are not predicated the custom chassis standards on any use of weight reduction. We have learned that manufacturers of concrete mixers, refuse trucks, and some high end buses have already made extensive use of lightweighting technologies in the baseline fleet. We also received persuasive comment cautioning us not to base the school bus standards on weight reduction due to potential conflicts with safety standards. In considering this information, we are allowing all vehicles certified using custom chassis regulatory subcategory identifiers to make use of weight reduction as a compliance flexibility. We received compelling comment from UCS that weight reduction should be considered feasible for transit buses. Upon consideration of this comment as well as information regarding the preponderance of city buses with overloaded axles, we are predicated standard stringency for transit buses on use of aluminum wheels at the same adoption rate as for the primary program. See the RIA at Chapter 2.9.5.1.5 for more information about transit bus axles.

(vi) Electrified Accessory Packages

The agencies are predicated the final vocational vehicle standards in part on an adoption rate of five percent in MY 2021 of an electrified accessory package that achieves one percent fuel efficiency improvement. The discussion in Section V.C.(1)(a)(vi) describes some pre-defined e-accessory improvements that are available in GEM for all vocational vehicles. In MY 2024 we increase this adoption rate to ten percent, and in MY

2027 the projected adoption rate is 15 percent, applicable in all subcategories excluding custom chassis. Although we believe some components could be electrified for some custom chassis, we do not have sufficient information to estimate an incremental cost associated with electrifying the more complex systems on custom chassis such as buses, or to project a specific adoption rate for this type of improvement.

(vii) Tire Pressure System Packages

The agencies are predicating the vocational vehicle standards in part on

widespread adoption of tire pressure monitoring systems. These are readily accepted by fleets as a cost-effective safety and fuel-saving measure. Because there may be some minor challenges in applying this technology to some vehicles where the payload and duty cycle lead to very high tire temperatures and pressures (as described above), we are applying a lower adoption rate to Urban and Multi-purpose vehicles than to Regional vehicles, as shown in Table V–23. We are applying similarly lower adoption rates for refuse trucks and

transit buses. We are not predicating the emergency vehicle or cement mixer standards on adoption of TPMS.

We are predicating the optional school bus, coach bus, transit bus, and refuse truck standards in part on limited adoption of automatic tire inflation systems (ATIS), as shown in Table V–23. These are more costly than TPMS, and require an onboard air supply and sometimes extensive plumbing of air lines.

TABLE V–23—VOCATIONAL TIRE PRESSURE SYSTEM ADOPTION RATES

Technology	TPMS			ATIS	
	MY 2021	MY 2024	MY 2027	MY 2021	MY 2027
Regional	60	75	90		
Multi-Purpose	50	65	80		
Urban	40	55	70		
School	70		80		20
Coach	50		75	10	25
Transit	40		50	10	20
Refuse	40		50	10	15
Motor Home	60		90		

(c) GEM Inputs for Derivation of Vocational Vehicle Standards

To account for engine-level improvements consistent with those projected to meet Phase 2 vocational engine standards, and which will be reflected over the GEM vehicle test cycles, the agencies developed a suite of fuel consumption maps for use with the GEM: One set of maps that represent engines meeting the MY 2021 vocational diesel engine standards, a second set of maps representing engines meeting the MY 2024 vocational diesel engine standards, and a third set of maps representing engines meeting the MY 2027 vocational diesel engine standards.⁴⁴¹ By incorporating the engine technology packages projected to be adopted to meet the Phase 2 vocational CI engine standards, the agencies employed GEM engine models in deriving the stringency of the Phase 2 CI-powered vocational vehicle standards. Similarly, to account for the performance of Phase 2 SI engines in deriving the stringency of the Phase 2 SI-powered vocational vehicle standards, the agencies employed our baseline SI GEM engine model. The extra engine technology on which the Phase 2 SI vocational vehicle standards

are based was applied in post-processing the GEM results, not modeled with an improved GEM map. See the RIA Chapter 2.9.1 for more details about the vocational engines used in standard-setting.

The derivation of the vocational vehicle standards incorporates several methods because some GEM inputs lend themselves to fleet-average values, some are vehicle specific (either on or off) and some improvements are not directly modeled in GEM. For each model year of standards, the agencies derived a scenario vehicle for each subcategory using the future model year engine map with fleet average input values for tire rolling resistance and weight reduction. For example, the MY 2021 HHD weight reduction input value was derived as follows: 250 pounds times 10 percent adoption yields 25 pounds. Those scenario vehicle performance results were combined in a post-process method with subcategory-specific improvements from idle reduction, axle disconnect, torque converter lockup, and transmission automation, using directly modeled GEM improvements comparing results with these technologies on or off the scenario vehicle. Subsequently, these performance values were combined

with estimated improvement values of technologies not modeled in GEM, including TPMS, hybrids, and transmission gear efficiency.

The set of fleet-average inputs for tire CRR and weight reduction for MY 2021, as modeled in GEM is shown in Table V–24, along with the respective adoption rates for idle reduction, axle disconnect, and torque converter lockup. The agencies derived the level of the MY 2024 standards by using the GEM inputs and adoption rates shown in Table V–25, below. The agencies derived the level of the MY 2027 standards by using the GEM inputs and adoption rates shown in Table V–26, below. Post-processing improvements for technologies not directly modeled, including TPMS, e-accessories, hybrids, and axle and transmission improvements are presented as a combined driveline improvement factor in Table V–27, below. The values in this table for SI-powered vocational vehicles include improvements due to adoption of SI engine technology. The methodology for estimating these improvements is described in the RIA Chapter 2.9.1. The final standards are presented in Table V–4 through Table V–9.

⁴⁴¹ See Section II.D.2 of this Preamble for the derivation of the engine standards.

(d) Role of Fleet Averaging and Constraints in Vocational Vehicle Standards

In part to avoid potentially creating incentives to misclassify vehicles, the agencies proposed to “equalize” the standards for each of the subcategories. 80 FR 40308. Thus, at proposal, the standards for the Regional, Multipurpose, and Urban subcategories reflected the arithmetic mean of the Regional, Multipurpose and Urban stringency levels (*i.e.*, all three drive cycle subcategory percent improvements averaged together) in each weight class.⁴⁴² Most commenters criticized this proposed approach. For example, Navistar commented that equalization could inappropriately benefit one manufacturer over another based on their product mix. We also note that the equalization process, if adopted, would have made the standards for the Regional vehicles unattainable using the technology pathway identified by the agencies, thus motivating manufacturers to select less appropriate test cycles for vehicles that are designed for Regional service. Therefore, we have decided not to apply “equalization” for finalizing the

vocational vehicle standards. Instead, we have developed the final vocational vehicle standards using the same methodology as for all of the other Phase 2 standards, where we apply fleet average technology mixes to fleet average baseline vehicle configurations, and each average baseline and technology mix is unique for each vehicle subcategory. Along with this standard-setting approach, the agencies are also adopting certain interim constraints on the otherwise generally manufacturer-selected assignment of vehicle configurations to one of the three drive cycle subcategories, as explained in Section V.D.(1)(e) below.

Elsewhere in this rulemaking we present overall costs and benefits, which are based on our projected distribution of vocational vehicles in each subcategory. This projection includes our most updated population distributions by weight class, which we have adjusted in part in response to comments on the draft NREL report in the NODA and based on an analysis of telematics data from Ryder’s leased vehicles. We intend to monitor whether our projection of distribution of vehicles among subcategories is consistent with outcomes. Under the three drive cycle subcategory structure, manufacturers must use good engineering judgment

(subject to the provisions of 40 CFR 1068.5) to choose a subcategory for each vehicle configuration that represents the type of operation the vehicle is configured to experience in use, and the agencies expect the manufacturer and customer to specify a technology mix that is most effective for that vehicle’s likely operation. In other words, as long as manufacturers work with their customers, the general rule describing this greater flexibility in choice of subcategory could be that the “customer knows best.” In fact, our standards are predicated on the premise that willful misclassification not reflecting good engineering judgment will be rare, and thus environmentally inconsequential.

In considering our approach for setting the final standards, we compared the relative stringencies in each subcategory with each respective baseline, and we observed that Regional vehicles are generally able to achieve the smallest percent improvement from the lowest (most efficient) baseline. By contrast, the Urban vehicles are generally able to achieve the greatest percent improvement from the highest (least efficient) baseline. We are not particularly concerned that adopting final standards with these unequal percent improvements poses a danger of losing environmental benefits from this

⁴⁴² See proposed rules at 80 FR 40308, July 13, 2015.

program, as long as vehicle configurations are properly classified at the time of certification. To test the potential impacts of misclassification, we compared the performance of each of our baseline configurations over all three drive cycles. This analysis is presented in a memorandum to the docket.⁴⁴³ Results for LHD and MHD weight classes were generally consistent with the rule's projections across each drive cycle. Results for HHD were equivocal in some instances, particularly for our baseline vehicles equipped with manual transmissions. This issue appears to be related to both the difference in the weighting of time spent in the drive idle mode in the Regional versus Urban and Multi-purpose drive cycles, and whether or not automatic transmissions are part of a baseline. In the analysis, that combination of circumstances showed how manual transmission-equipped vehicles could potentially become credit generators without any further addition of technology, if certified to the Urban or Multi-purpose cycles. The agencies are concerned that if this circumstance were to be left unconstrained, it could create an incentive to misclassify some Regional vehicles into one of the other two drive cycle subcategories, even though manual transmissions are generally best suited for Regional driving patterns, as discussed further below.

In light of this analysis, and consistent with recent comments from chassis manufacturers mentioned above in Section V.B.(1)(a), the agencies are adopting some constraints to the otherwise generally manufacturer-selected assignment of vocational chassis to regulatory subcategories. These constraints are described in Section V.D.(1)(e). A subset of the constraints prevents inappropriate classification based on transmission type. These constraints restrict classification options where a vocational vehicle is certifying with a manual transmission or in some cases an automated manual transmission. We are adopting these constraints as interim provisions in response to

manufacturers' concerns that the manual transmission constraints could present competitive disadvantages, where different manufacturers produce very different sales mixes of vehicles equipped with different transmission types.⁴⁴⁴ However, at this time the final program structure, including these constraints, will remain in place unless and until the agencies determine that revisions to the vocational vehicle program structure are warranted, in which case the agencies would undertake a notice and comment rulemaking proposing to amend the programmatic structure, consistent with such a determination.

It is important to clarify that we would consider all relevant factors together before deciding whether to propose any revisions. If we find that a significant discrepancy arises between our projections and outcomes, such that our estimated GHG and fuel consumption benefits are not being achieved because of the program structure, we may revisit relevant aspects of the program structure, including the drive cycles, subcategories and classification constraints. If we propose to revise the structure in the future, it might also be necessary to propose revising the numerical values of the standards to maintain equivalence with the final stringency being established in this rulemaking. We would of course find it acceptable if manufacturers implemented more cost-effective technologies than we projected, while still achieving the projected reductions in use. Similarly, if the structure results in manufacturers generally adopting the projected cost-effective technologies on the appropriate vehicles, but somehow this fails to fully achieve the projected reductions in use, we do not believe revisions necessarily would be warranted.

(e) Technology Package Costs Associated With Primary Vocational Vehicle Standards

The agencies have estimated the costs of the technologies that could be used to comply with the final Phase 2

vocational vehicle standards. The estimated costs are shown in Table V–28 for MY 2021, in Table V–29 for MY 2024, and Table V–30 for MY 2027. Fleet average costs are shown for light, medium and heavy HD vocational vehicles in each duty-cycle-based subcategory—Urban, Multi-Purpose, and Regional. As shown in Table V–28, in MY 2021 these range from approximately \$900 for MHD and LHD Regional vehicles, up to \$2,600 for HHD Regional vehicles. Those two lower-cost packages reflect zero hybrids, and the higher-cost package reflects significant adoption of automated transmissions. Many changes have been made to the cost estimates since proposal. In the RIA Chapter 2.12.2, the agencies present vocational vehicle technology package costs differentiated by MOVES vehicle type. These costs do not indicate the per-vehicle cost that may be incurred for any individual technology. For more specific information about the agencies' estimates of per-vehicle costs, please see the RIA Chapter 2.11. The engine costs listed represent the cost of an average package of diesel engine technologies as set out in Section II. Individual technology adoption rates for engine packages are described in Section II.D. For gasoline vocational vehicles, the agencies are projecting adoption of Level 2 engine friction reduction plus cylinder deactivation (*i.e.*, all engine improvements are reflected exclusively in the vehicle standard) for an estimated \$138 added to the average SI vocational vehicle package cost beginning in MY 2021. Further details on how the SI vocational vehicle costs were estimated are provided in the RIA Chapter 2.9.

The details behind all these costs are presented in RIA Chapter 2.11, including the markups and learning effects applied and how the costs shown here are weighted to generate an overall cost for the vocational segment. These estimates have changed significantly from those presented in the proposal, due to changes in projected technology adoption rates as well as changes in direct costs that reflect comments received.

Notes:

^aCosts shown are for the 2021 model year and are incremental to the costs of a vehicle meeting the Phase 1 standards. These costs include indirect costs via markups along with learning impacts. For a description of the markups and learning impacts considered in this analysis and how it impacts technology costs for other years, refer to Chapter 2 of the RIA (see RIA 2.11).

^bNote that values in this table include adoption rates. Therefore, the technology costs shown reflect the average cost expected for each of the indicated vehicle classes. To see the actual estimated technology costs exclusive of adoption rates, refer to Chapter 2 of the RIA (see RIA 2.11 in particular).

^cEngine costs are for a light HD, medium HD or heavy HD diesel engine. We are projecting \$138 of additional costs beyond Phase 1 for gasoline vocational engines.

^dEPA's air conditioning standards are presented in Section V.C above.

^eOther incremental technology costs include electrified accessories and advanced shift strategy.

The estimated fleet average vocational vehicle package costs are shown in Table V-29 for MY 2024. As shown, these range from approximately \$1,300 for MHD and LHD Regional vehicles, up to \$4,000 for HHD Regional vehicles.

The increased costs above the MY 2021 values reflect increased adoption rates of individual technologies, while the individual technology costs are generally expected to remain the same or decrease, as explained in the RIA

Chapter 2.11. The engine costs listed represent the average costs associated with the MY 2024 vocational diesel engine standard described in Section II.D.

Total	1,959	2,018	1,272	2,082	2,110	1,274	2,932	3,813	4,009

Notes:

^aCosts shown are for the 2024 model year and are incremental to the costs of a vehicle meeting the Phase 1 standards. These costs include indirect costs via markups along with learning impacts. For a description of the markups and learning impacts considered in this analysis and how it impacts technology costs for other years, refer to Chapter 2 of the RIA (see RIA 2.11).

^bNote that values in this table include adoption rates. Therefore, the technology costs shown reflect the average cost expected for each of the indicated vehicle classes. To see the actual estimated technology costs exclusive of adoption rates, refer to Chapter 2 of the RIA (see RIA 2.9 in particular).

^cEngine costs are for a light HD, medium HD or heavy HD diesel engine. We are projecting \$136 additional costs beyond Phase 1 for gasoline vocational engines.

^dEPA's air conditioning standards are presented in Section V.C above.

^eOther incremental technology costs include electrified accessories and advanced shift strategy.

The estimated fleet average vocational vehicle package costs are shown in Table V-30 for MY 2027. As shown,

these range from approximately \$1,500 for MHD and LHD Regional vehicles, up to \$5,700 for HHD Regional vehicles.

These per-vehicle technology package costs were averaged using our projections of vehicle populations in the

nine regulatory subcategories and do not correspond to the MOVES vehicle types. The engine costs shown represent the average costs associated with the MY 2027 vocational diesel engine standard described in Section II.D.

Purchase prices of non-custom vocational vehicles can range from \$60,000 for a light heavy-duty stake-bed landscape truck to over \$300,000 for a

heavy heavy-duty boom truck. The costs of the vocational vehicle standards can be put into perspective by comparing estimated package costs with typical prices for those vehicles. For example, a package cost of \$3,000 on a \$60,000 landscaping truck represents an incremental increase of about five percent of the vehicle purchase price.

Similarly, a package cost of \$4,000 on a \$300,000 boom truck represents an incremental increase of less than two percent of the vehicle purchase price. The vocational vehicle industry characterization report in the docket includes additional examples of vehicle prices for a variety of vocational applications.⁴⁴⁵

Notes:

^a Costs shown are for the 2027 model year and are incremental to the costs of a vehicle meeting the Phase 1 standards. These costs include indirect costs via markups along with learning impacts. For a description of the markups and learning impacts considered in this analysis and how it impacts technology costs for other years, refer to Chapter 2 of the RIA (see RIA 2.11).

^b Note that values in this table include adoption rates. Therefore, the technology costs shown reflect the average cost expected for each of the indicated vehicle classes. To see the actual estimated technology costs exclusive of adoption rates, refer to Chapter 2 of the RIA (see RIA 2.9 in particular).

^c Engine costs are shown for a light HD, medium HD or heavy HD diesel engine. For gasoline-powered vocational vehicles we are projecting \$125 of additional engine-based costs beyond Phase 1.

^d EPA's air conditioning standards are presented in Section V.C above.

^e Other incremental technology costs include electrified accessories and advanced shift strategy.

(f) Custom Chassis Cost Estimates

The agencies have performed the above-described cost analysis using the assumption that all custom chassis vocational vehicles are certified to the primary standards, with full technology packages and use of the regular Phase 2 GEM. In terms of costs, we expect that a manufacturer will choose to certify a vehicle family to the optional custom chassis standards only if it is less costly to do so. The cost-benefit analysis found in the RIA Chapter 7 presents some estimates of what the technology package costs of the primary standards are in terms of MOVES vehicle types. For the MOVES types where a custom chassis option is available, these are conservatively high cost estimates. Table 6 and Table 7 of the RIA Executive Summary present estimates of average custom chassis technology packages associated with the final

optional standards in MY 2021 and MY 2027, respectively.

The agencies are not aware of any custom chassis manufacturer that produces engines. Thus, the engine costs will be borne by engine manufacturers. While some of the added engine costs may be passed on to vehicle manufacturers, and some vehicle costs may be passed on to owners/operators, the overall technology costs of the custom chassis standards are significantly less than the Phase 2 vocational vehicle technology costs, which, as shown directly below, are highly cost-effective.

(3) Consistency of the Vocational Vehicle Standards With the Agencies' Legal Authority

NHTSA and EPA project these standards to be achievable within known design cycles, and we believe these standards, although technology-advancing, will allow many different

paths to compliance in addition to the technology paths on which standard stringency is predicated. These standards are predicated on manufacturers implementing technologies that we expect will be available in the time frame of these final rules. We are projecting that most vehicles can adopt certain of the technologies. For example, we project a 70 to 90 percent application rate for TPMS. However, for other technologies, such as electrified accessories, we are projecting an adoption rate of 15 percent. These standards offer manufacturers the flexibility to apply the technologies that make sense for their business and for customer needs.

As discussed above, average per-vehicle costs associated with the 2027 MY standards are projected to be generally less than five percent of the overall price of a new vehicle. The annual cost-effectiveness of these vocational vehicle standards in dollars

⁴⁴⁵ See Heavy Duty Vocational Vehicle Industry Characterization, EPA Contract No. EP-C-12-011, September 2013.

per metric ton is presented in the RIA Chapter 7 in Table 7–47. As shown in that table, without fuel savings the cost per metric ton of the final vocational vehicle standards in calendar year 2021 is \$710, decreasing to \$100 by 2030. The cost effectiveness estimated for heavy-duty pickup trucks and vans in this rulemaking is presented in Table 7–46 in that same chapter of the RIA. Those Phase 2 standards have an estimated annual cost per metric ton without fuel savings of \$2,800 in 2020, decreasing to \$110 (about the same as for vocational) by calendar year 2030. The annual cost per ton of the MY 2017–2025 light-duty greenhouse gas standards for pickup trucks as reported in 2010 dollars without fuel savings is \$430 in calendar year 2020, decreasing to \$142 in 2030.⁴⁴⁶ The agencies have found these standards to be highly cost effective. In addition, the vocational vehicle standards are clearly effective from a net benefits perspective (see RIA Chapter 11.2). Therefore, the agencies regard the cost of the final standards as reasonable, even without considering that the costs are recovered due decreased fuel consumption.

The agencies note that while the projected costs are significantly greater than the costs projected for Phase 1, we still consider these costs to be reasonable, especially given that the first vehicle owner may see the technologies pay for themselves in many cases. As discussed above, the usual period of ownership for a vocational vehicle reflects a lengthy trade cycle that may often exceed seven years. For most vehicle types evaluated, the cost of these technologies, if passed on fully to customers, will likely be recovered within four years or less due

to the associated fuel savings, as shown in the payback analysis included in Section IX.M and in the RIA Chapter 7.1. Specifically, in RIA Chapter 7.2.4, a summary is presented with estimated payback periods for each of the MOVES vocational vehicle types, using the annual vehicle miles traveled from the MOVES model for each vehicle type. As noted above, the cost analysis presented for this rulemaking assumes that all vocational vehicles are certified to the primary standard. Using this assumption, the vocational vehicle type with the shortest payback is intercity buses (less than one year), while most other vehicles (with the exception of school buses and motor homes) are projected to see paybacks in the fourth year or sooner. We expect that manufacturers will certify to the optional custom chassis standards where it is more cost-effective to do so; therefore, our analysis may be overly conservative where it indicates very long paybacks for some vocational vehicles.

The agencies note further that although the rules are technology-advancing (especially with respect to driveline improvements) and the estimated costs for each subcategory vary considerably (by a factor of five in some cases), these costs represent only one of many possible pathways to compliance for manufacturers. Manufacturers retain leeway to develop alternative compliance paths, increasing the likelihood of the standards' successful implementation. Based on available information, the agencies believe the final vocational vehicle standards are technically feasible within the lead time provided, are cost effective while accounting for the fuel savings

(see RIA Chapter 7.1.4), and have no apparent adverse collateral potential impacts (e.g., there are no projected negative impacts on safety or vehicle utility).

The final standards thus appear to represent a reasonable choice under section 202(a) of the CAA and are maximum feasible under NHTSA's EISA authority at 49 U.S.C. 32902(k)(2). The agencies believe that the final standards are consistent with their respective authorities.

(4) Alternative Vocational Vehicle Standards Considered

The agencies developed and considered other alternative levels of stringency for the Phase 2 program. The results of the analysis of these alternatives, and comments received on alternatives, are discussed below in Section X of the Preamble and the RIA Chapter 11. For vocational vehicles, the agencies developed alternatives as shown in Table V–31. The agencies are not adopting standards reflecting Alternative 2, because as already described, technically feasible standards are available that provide for greater emission reductions and reduced fuel consumption than provided under Alternative 2. The agencies are not adopting standards reflecting Alternative 4 or Alternative 5 because we do not believe these standards to be feasible considering lead time and other relevant factors. Nevertheless, we have reevaluated each of the technology projections proposed for Alternative 4 and have determined that some engine and tire reductions will be feasible on the Alternative 4 timeline.

TABLE V–31—SUMMARY OF ALTERNATIVES CONSIDERED FOR THE FINAL RULEMAKING

Alternative 1 and 1b	No action alternatives
Alternative 2	Less stringent than the preferred alternative in the proposal, applying off-the-shelf technologies.
Final HD Phase 2 program	Fully phased-in by MY 2027.
Alternative 4	Same stringency as preferred alternative in the proposal, phasing in by MY 2024.
Alternative 5	More stringent alternative, based on higher adoption rates of advanced technologies.

D. Compliance Provisions for Vocational Vehicles

We are adopting many changes in the compliance provisions for vocational vehicles compared with what we proposed, as described in this section.

(1) Application and Certification Process

The agencies are adopting changes in the final Phase 2 version of GEM, as described in Section II of this Preamble. Below we provide cross-references to test procedures either that are either required or optional, for generation of Phase 2 GEM input values. See Section

II.D.1 for details of engine testing and GEM inputs for engines.

As described above in Section I, the agencies will continue the Phase 1 compliance process in terms of the manufacturer requirements prior to the effective model year, during the model year, and after the model year. The information that will be required to be submitted by manufacturers is set forth

⁴⁴⁶ See Chapter 5.3 of the final RIA for the MY 2017–2025 Light-Duty GHG Rule, available at

<http://www3.epa.gov/otaq/climate/documents/420r12016.pdf>.

in 40 CFR 1037.205, 49 CFR 537.6, and 49 CFR 537.7. EPA will continue to issue certificates upon approval based on information submitted through the VERIFY database (see 40 CFR 1037.255). End of year reports will continue to include the GEM results for all of the configurations built, along with credit/deficit balances, if applicable (see 40 CFR 1037.250 and 1037.730).

(a) GEM Inputs

In Phase 1, there were two inputs to GEM for vocational vehicles:

- Steer tire coefficient of rolling resistance, and
- Drive tire coefficient of rolling resistance

As discussed above in Section II and III.D, there are several additional inputs that we are adopting for Phase 2. In addition to the steer and drive tire CRR, the inputs include the following:

- Engine input file with fuel map, full-load torque curve, and motoring curve,
- Transmission input file including architecture type, gear number and ratios, and minimum lockup gear for transmissions with torque converters,
 - Drive axle ratio,
 - Axle configuration,
 - Tire size in revs/mi for drive and steer tires,
 - Idle Reduction,
 - Weight Reduction,
 - Vehicle Speed Limiter,
 - Aerodynamic Drag Area, and
 - Pre-defined technology inputs for Accessory Load and Tire Pressure Systems

(i) Driveline Inputs

As with tractors, for each engine family, engine fuel maps, full load

torque curve, and motoring curve will be generated by engine manufacturers and supplied to chassis manufacturers in a format compatible with GEM. The test procedures for the torque and motoring curves are found in 40 CFR part 1065. Section II.D.1.b describes these procedures as well as the procedures for generating the engine fuel maps. We require the steady state map approach for the 55 and 65 mph cruise speed cycles, while the cycle average approach is required for the ARB transient cycle. As an option, the cycle average map may also be used for 55 and 65 mph cruise speed cycles. Also similar to tractors, transmission specifications will be input to GEM. Any number of gears may be entered with a numerical ratio for each, and transmission type must be entered as either a Manual, Automated Manual, or Automatic transmission.

As part of the driveline information needed to run GEM, drive axle ratio will be a user input. If a configuration has a two-speed axle, the agencies are adopting regulations to instruct a manufacturer to enter the ratio that is expected to be engaged for the greatest driving distance. We requested comment on whether the agencies should allow this choice, and what the GEM input instructions should be. Both Dana and Meritor commented that there should be an option to recognize two-speed axles, but neither axle supplier offered a preference for how the agencies should implement this. Two-speed axles are typically specified for heavy-haul vehicles, where the higher numerical ratio axle is engaged during transient driving conditions and to deliver performance needed on work

sites, while the lower numerical ratio axle may be engaged during light-load highway driving.

Tire size is a Phase 2 input to GEM that is necessary for the model to simulate the performance of the vehicle. As a result of comment and further technical analysis, we are adopting the tire size input as measured in revs/mile, rather than the measure of loaded radius in meters, as was proposed. The RIA Chapter 3 includes a description of how to measure tire size. For each model and nominal size of a tire, there are numerous possible sizes that could be measured, depending on whether the tire is new or “grown,” meaning whether it has been broken in for at least 200 miles. Size can also vary based on load and inflation levels, air temperature, and tread depth. The agencies requested comment on aspects of measuring and reporting tire size. The revised test procedure is described in the RIA Chapter 3.3.4.

For manufacturers electing to certify a vocational vehicle to the optional custom chassis standards, none of the above driveline inputs are applicable. In this case manufacturers must input one of the custom chassis regulatory subcategory identifiers shown in Table V–32. After the remaining input fields are either completed with values or N/A, GEM will simulate the vehicle by calling the default engine and transmission files, tire size, and axle radius from the GEM library. The following subsections describe the required and optional inputs for custom chassis.

TABLE V–32—CUSTOM CHASSIS SUBCATEGORY NAMES

Vehicle type	Regulatory subcategory GEM identifier	Default weight class and duty cycle
Motor Home	MHD_CC_MH	MHD Regional.
School Bus	MHD_CC_SB	MHD Urban.
Coach Bus	HHD_CC_CB	HHD Regional.
Emergency Vehicle	HHD_CC_EM	HHD Urban.
Concrete Mixer	HHD_CC_CM	HHD Urban.
Transit and Other bus	HHD_CC_OB	HHD Urban.
Refuse Truck	HHD_CC_RF	HHD Urban.

The agencies requested comments on the merits of using an equation-based compliance approach for emergency vehicle manufacturers, similar to the approach for trailer manufacturers described in Section IV.F. CARB commented in support of an equation-based compliance approach, but in the same comment they also expressed support for using a Phase 1-style GEM interface with a default engine

simulated in GEM as appropriate for the emergency vehicle category. We received adverse comment on the equation-based approach from Daimler, because they believed it would make the compliance process more complex if some vehicles needed to be tracked differently. Our intent in soliciting comment on an equation-based approach was to assess whether running GEM was a burden for non-diversified

manufacturers of low-technology vehicles. Because we received sufficient support from non-diversified manufacturers that a simplified GEM would meet their needs, we did not pursue an equation-based approach.

The final certification approach is consistent with the approach recommended by the Small Business Advocacy Review Panel, which believed it will be feasible for small emergency

vehicle manufacturers to install a Phase 2-compliant engine, but recommended a simplified certification approach to reduce the number of required GEM inputs.

(ii) Idle Reduction Inputs

The agencies proposed two different idle reduction inputs for vocational vehicles: Neutral idle and stop-start. Based on comment, we are adding a third type of idle reduction input: Automatic engine shutdown. Based on user inputs derived from engine testing described in Section II and RIA Chapter 3.1, GEM will calculate CO₂ emissions and fuel consumption at both zero torque (neutral idle) and with torque set to Curb-Idle Transmission Torque for automatic transmissions in “drive” (as described in the RIA Chapter 3.4.2.3) for use in the CO₂ emission calculation in 40 CFR 1037.510(b). At proposal, neutral idle and stop-start were not recognized during the ARB transient cycle, they were recognized only during the separate idle cycle. The agencies received comments requesting recognition of neutral idle during the ARB transient test cycle. We agree this is desirable and have adopted changes in GEM to accomplish this. Also, with the adoption of the alternative engine mapping procedure for the ARB transient cycle, the computation for idle reduction has changed. Please see RIA

Chapter 4.4.1.7 for a description of how GEM recognizes idle reduction.

For vocational custom chassis certified to the optional standards, all three idle reduction inputs will be available, however, the computation will be based on the EPA default engine. As described in the GEM User Guide, users will enter Y or N, and GEM will return a predefined improvement.

(iii) Weight Reduction Inputs

In Phase 1, the agencies adopted tractor regulations that provided manufacturers with the ability to utilize high strength steel and aluminum components for weight reduction without the burden of entering the curb weight of every tractor produced. In Phase 2, the agencies are adopting a lookup table of lightweight components for use in certifying vocational vehicles, similar to the process for tractors. As noted above, the agencies will recognize weight reduction by allocating one half of the weight reduction to payload in the denominator, while one half of the weight reduction will be subtracted from the overall weight of the vehicle in GEM.

The agencies are adopting lookup values for components on vocational vehicles in all HD weight classes. Components available for vocational vehicle manufacturers to select for weight reduction are shown below in

Table V–33, below. All of these weight reduction inputs will be available for manufacturers of custom chassis certifying to the optional standards. We received comments from Allison Transmission noting that aluminum transmission cases and clutch housings are standard for automatic transmissions so we agree it is inappropriate to include these components in the lookup table. We have revised the values in response to adverse comments from AISI, and after reevaluating information available at proposal. Although we are not projecting any adoption of permanent 6x2 axles for non-custom vocational vehicles, if a manufacturer chooses to apply this technology for class 8 vocational vehicles, users may enter an appropriate weight reduction compared to the traditional 6x4 axle configuration.⁴⁴⁷ We received adverse comments on the proposal to assign a fixed weight increase to natural gas fueled vehicles to reflect the weight increase of natural gas fuel tanks versus gasoline or diesel tanks. Based on comments and further technical analysis, we have determined that to provide equitable treatment to technologies, we will not require a weight penalty for any technology applied to achieve certification in Phase 2. We accounted for adoption of weight-increasing technologies in our MOVES modeling.

TABLE V–33—PHASE 2 WEIGHT REDUCTION TECHNOLOGIES FOR VOCATIONAL VEHICLES

Component	Material	Vocational vehicle class		
		Class 2b–5	Class 6–7	Class 8
Axle Hubs—Non-Drive	Aluminum	40		40
Axle Hubs—Non-Drive	High Strength Steel	5		5
Axle—Non-Drive	Aluminum	60		60
Axle—Non-Drive	High Strength Steel	15		15
Brake Drums—Non-Drive	Aluminum	60		60
Brake Drums—Non-Drive	High Strength Steel	42		42
Axle Hubs—Drive	Aluminum	40		80
Axle Hubs—Drive	High Strength Steel	10		20
Brake Drums—Drive	Aluminum	70		140
Brake Drums—Drive	High Strength Steel	37		74
Suspension Brackets, Hangers	Aluminum	67		100
Suspension Brackets, Hangers	High Strength Steel	20		30
Crossmember—Cab	Aluminum	10	15	15
Crossmember—Cab	High Strength Steel	2	5	5
Crossmember—Non-Suspension	Aluminum	15	15	15
Crossmember—Non-Suspension	High Strength Steel	5	5	5
Crossmember—Suspension	Aluminum	15	25	25
Crossmember—Suspension	High Strength Steel	6	6	6
Driveshaft	Aluminum	12	40	50
Driveshaft	High Strength Steel	5	10	12
Frame Rails	Aluminum	120	300	440
Frame Rails	High Strength Steel	40	40	87
Wheels—Dual	Aluminum	150	150	250
Wheels—Dual	High Strength Steel	48	48	80
Wheels—Wide Base Single	Aluminum	294	294	588

⁴⁴⁷ See NACFE Confidence Findings on the Potential of 6x2 Axles.

TABLE V-33—PHASE 2 WEIGHT REDUCTION TECHNOLOGIES FOR VOCATIONAL VEHICLES—Continued

Component	Material	Vocational vehicle class		
		Class 2b-5	Class 6-7	Class 8
Wheels—Wide Base Single	High Strength Steel	168	168	336
Permanent 6x2 Axle Configuration	Multi	N/A	N/A	300

(iv) Other Inputs

Certifying manufacturers may enter values in GEM as applicable for vehicle speed limiters, fairings to reduce aerodynamic drag area, electrified accessories, and tire pressure systems where such features meet the criteria in the regulations at 40 CFR 1037.520.

(b) Test Procedures

Powertrain families are defined in Section II.C.3.b, and powertrain test procedures are discussed in the RIA Chapter 3.6. The results from testing a powertrain configuration using the matrix of tests described in RIA Chapter 3.6 can be applied broadly across all vocational vehicles in which that powertrain will be installed. Powertrain test results become a GEM input file that replaces both the engine input file and transmission input file.

As in Phase 1, the rolling resistance of each tire will be measured using the ISO 28850 test method for drive tires and steer tires planned for fitment to the vehicle being certified. Once the test CRR values are obtained, a manufacturer will declare TRRLs (which may be equal to or higher than the measured values) for the drive and steer tires separately to be input into the GEM. For Phase 2 vocational vehicles, GEM will distribute the vehicle load with 30 percent of the load over the steer tires and 70 percent of the load over the drive tires. With these data entered, the amount of GHG reduction attributed to tire rolling resistance will be incorporated into the overall vehicle compliance value.

The final Phase 2 GEM will accept as inputs results from a transmission efficiency test. A procedure for this was discussed in the NPRM, and received favorable comment. The transmission efficiency test will be optional, but will allow manufacturers to reduce the CO₂ emissions and fuel consumption by designing better transmissions with lower friction due to better gear design and/or mandatory use of better lubricants.

In lieu of a fixed value for low friction axle lubricants as was proposed, the agencies are adopting an axle efficiency test procedure, as was discussed in the NPRM. See 80 FR 40323. The axle efficiency test will be optional, but will allow manufacturers to reduce CO₂

emissions and fuel consumption through improved axle gear designs and/or mandatory use of low friction lubricants. The agencies are not finalizing any other paths to recognize low friction axle lubricants.

(c) Useful Life and In-Use Standards

Section 202(a)(1) of the CAA specifies that emission standards are to be applicable for the useful life of the vehicle. The standards that EPA and NHTSA are adopting will apply to individual vehicles and engines at production and in use. NHTSA is not adopting in-use standards for vehicles or engines.

Manufacturers may be required to submit, as part of the application for certification, an engineering analysis showing that emission control performance will not deteriorate during the useful life, with proper maintenance. If maintenance will be required to prevent or minimize deterioration, a demonstration may be required that this maintenance will be performed in use. See 40 CFR 1037.241.

EPA will continue the Phase 1 approach to adjustment factors and deterioration factors for vehicles. The technologies on which the Phase 1 vocational vehicle standards were predicated were not expected to have any deterioration of GHG effectiveness in use. However, the regulations provided a process for manufacturers to develop deterioration factors (DF) if they needed. We anticipate that some hybrid powertrain systems may experience some deterioration of effectiveness with age of the energy storage device. We believe the regulations in place currently provide adequate instructions to manufacturers for developing DF where needed. We received comments from Daimler on deterioration factors for engines and the process for extrapolating where DF's are nonlinear. See Section 3.7 of the RTC. Allison Transmission commented that the amount of credits generated for a hybrid system should be dependent, in part, on design limits of batteries. We do not believe any changes are needed because the regulations do account for this by basing the FELs on the highest emissions during the useful life, including any effects from deterioration.

As with engine certification, a chassis manufacturer must design their vehicles to be durable enough to maintain compliance through the regulatory useful life of the vehicle. Factors influencing vehicle-level GHG performance over the life of the vehicle fall into two basic categories: Vehicle attributes and maintenance items. Each category merits different treatment from the perspective of assessing useful life compliance, as each has varying degrees of manufacturer versus owner/operator responsibility. The agencies require manufacturers to explain how they meet these requirements as part of certification.

For vocational vehicles, attributes generally refers to components that are installed by the manufacturer to meet the standard, whose reduction properties are assessed at the time of certification, and which are expected to last the full life of the vehicle with effectiveness maintained as new for the life of the vehicle with no special maintenance requirements. To assess useful life compliance, we will follow a design-based approach that will ensure that the manufacturer has robustly designed these features so they can reasonably be expected to last the useful life of the vehicle.

For vocational vehicles, maintenance items generally refers to items that are replaced, renewed, cleaned, inspected, or otherwise addressed in the preventative maintenance schedule specified by the vehicle manufacturer. Replacement items that have a direct influence on GHG emissions are primarily tires and lubricants, but may also include hybrid system batteries. Synthetic engine oil may be used by vehicle manufacturers to reduce the GHG emissions of their vehicles. Manufacturers may specify that these fluids be changed throughout the useful life of the vehicle. If this is the case, the manufacturer should have a reasonable basis that the owner/operator will use fluids having the same properties. This may be accomplished by requiring (in service documentation, labeling, etc.) that only these fluids can be used as replacements. We received comments from EMA asking us to consider maintenance costs for hybrids. In these final rules, we have quantified

maintenance costs for tire replacement, stop-start, axle lubrication, and hybrids, as described in Section IX.D and the RIA Chapter 7.1.

Aside from those technologies identified above, if the vehicle remains in its original certified condition throughout its useful life, it is not believed that GHG emissions will increase as a result of service accumulation. As in Phase 1, the agencies will therefore allow the use of an assigned deterioration factor of zero where appropriate in Phase 2; however this does not negate the responsibility of the manufacturer to ensure compliance with the emission standards throughout the useful life.⁴⁴⁸ Under both Phase 1 and the new Phase program, manufacturers must apply good engineering judgment when considering deterioration and may not ignore any evidence that the emissions performance will decline during actual use. The agencies may require vehicle manufacturers to provide engineering analyses at the time of certification demonstrating that vehicle attributes will last for the full useful life of the vehicle. We anticipate this demonstration would often need only show that components are constructed of sufficiently robust materials and design practices so as not to become dysfunctional under normal operating conditions.

In Phase 1, EPA set the useful life for engines and vehicles with respect to GHG emissions equal to the respective useful life periods for criteria pollutants. In April 2014, as part of the Tier 3 light-duty vehicle final rule, EPA extended the regulatory useful life period for criteria pollutants to 150,000 miles or 15 years, whichever comes first, for Class 2b and 3 pickup trucks and vans and some light-duty trucks (79 FR 23414, April 28, 2014). Class 2 through Class 5 heavy-duty vehicles subject to the GHG standards described in this section for vocational applications generally use the same kinds of engines, transmissions, and emission controls as the Class 2b and 3 vehicles that are chassis-certified to the criteria standards under 40 CFR part 86, subpart S. In Phase 2, EPA and NHTSA are adopting a useful life of 150,000 miles or 15 years for vocational vehicles at or below 19,500 lbs GVWR. In many cases, this will result in aligned useful-life values for criteria and GHG standards. Where this longer useful life is not aligned with the useful life that applies for criteria

standards (generally in the case of engine-based certification under 40 CFR part 86, subpart A), EPA may revisit the useful-life values for both criteria and GHG standards in a future rulemaking. For medium heavy-duty vehicles (19,500 to 33,000 lbs GVWR) and heavy heavy-duty vehicles (above 33,000 lbs GVWR) EPA will keep the useful-life values from Phase 1, which are 185,000 miles (or 10 years) and 435,000 miles (or 10 years), respectively. EPA received comments in support of this approach, including support for the numerical values and the overall process envisioned for achieving the long-term goal of adopting harmonized useful-life specifications for criteria pollutant and GHG standards that properly represent the manufacturers' obligation to meet emission standards over the expected service life of the vehicles.

We received comment on what policies we should adopt to address the situation where the engine and the vehicle are subject to emission standards over different useful-life periods. For example, a medium heavy-duty engine may power vehicles in weight classes ranging from 2b to 8, with correspondingly different regulatory useful lives for those vehicles. Please see Section I.F.2.f for a discussion of revisions made to the final regulations to address this situation. The Response to Comments also addresses this issue at Chapter 1.4.

(d) Definitions of Custom Chassis

Eligible emergency vehicles for Phase 2 purposes are ambulances and fire trucks. The agencies requested comment on aligning the definition of emergency vehicle for purposes of the Phase 2 program with the definition of emergency vehicle for purposes of the light-duty GHG provisions under 40 CFR 86.1818, which includes additional vehicles such as those used by law enforcement.⁴⁴⁹ Daimler commented in support of aligning these definitions of emergency vehicle. Daimler further requested the agencies consider adopting the same definition as in 13 CCR 1956.8(a)(6), the California regulations. We are adopting the narrow definition as was proposed, with agency discretion to apply these provisions to similar vehicles.

RVIA commented in favor of adopting a motor home definition consistent with NHTSA's definition at 49 CFR 571.3: *Motor home* means a multipurpose passenger vehicle with motive power that is designed to provide temporary residential accommodations, as

evidenced by the presence of at least four of the following facilities: Cooking; refrigeration or ice box; self-contained toilet; heating and/or air conditioning; a potable water supply system including a faucet and a sink; and a separate 110–125 volt electrical power supply and/or propane. The agencies are adopting a definition of motor home that is generally consistent with this, without specifying detailed features.

Since 2003, NHTSA has implemented a broad definition of school bus that includes multifunction school activity buses that don't have stop arms or flashing lights, need not be painted yellow, and do not have an upper weight limit. These are a category of school bus that must meet the school bus structural standards or the equivalent set forth in 49 Code of Federal Regulations Part 571, and the emergency exit requirements specified in FMVSS No. 217 for school buses, as well as FMVSS 222 for passenger seating and crash protection. This definition was created in part to allow for use of safe buses to transport school age children on trips other than those between home and school. The agencies are adopting Phase 2 provisions such that buses eligible to certify to the custom chassis school bus standards are those that meet NHTSA's definition of school bus, including multifunction school activity buses.⁴⁵⁰

The most definitive attribute we have identified to distinguish over-the-road coach buses from transit buses is whether passengers are permitted to stand while the vehicle is driving. Therefore the only buses permitted to certify to the final custom chassis coach bus standards are those subject to NHTSA's Occupant Crash Protection Rule.⁴⁵¹

Allied Specialty Vehicles (aka Rev Group) commented on the need for a clear distinction between transit buses and school buses.⁴⁵² If the pupils transported are not K–12 students, such as may be the case for buses serving college campuses, then the chassis may not be easily distinguishable from transit buses. The agencies are adopting provisions in Phase 2 such that buses not qualifying as eligible to certify as coach buses or school buses must meet the custom chassis standards for transit

⁴⁴⁸ For most technologies, manufacturers may presume zero deterioration unless good engineering judgment does not support such a presumption. For example, it would not be appropriate to presume no deterioration in hybrid battery performance.

⁴⁴⁹ See 40 CFR 86.1803–01 for the applicable definition of emergency vehicle.

⁴⁵⁰ See 68 FR 44892—Federal Motor Vehicle Safety Standards; Definition of Multifunction School Activity Bus; <https://www.govinfo.gov/content/pkg/FR-2003-07-31/pdf/03-19457.pdf>.

⁴⁵¹ See Occupant Crash Protection rule, November 25, 2013, 78 FR 70415, 49 CFR 571, FMVSS 208 <https://www.gpo.gov/fdsys/pkg/FR-2013-11-25/html/2013-28211.htm>, accessed February 2016.

⁴⁵² Phone conversation March 2016, see L. Steele phone log.

buses. Buses serving college campuses do not have the same design and safety restrictions as those intended to transport primary and secondary school children, and may apply the same technologies as general-purpose urban buses.

Therefore, we are requiring refuse trucks that do not compact waste to be certified to the primary vocational vehicle standards. Front-loading refuse collection vehicles tend to have a relatively low number of stops per day as they tend to collect waste from central locations such as commercial buildings and apartment complexes. Because these have a relatively low amount of PTO operation, we expect stop-start will be reasonably effective for these vehicles. Rear-loading and side-loading neighborhood waste and recycling collection trucks are the refuse trucks where the largest number of stop-start and neutral idle over-ride conditions are likely to be encountered. Because chassis manufacturers, even those with small production volumes and close customer relationships, do not always know whether a refuse truck will be a front-loader, rear-loader, or side loader, we are grouping these together in a subcategory.

We received comment on the need to clarify whether vehicles designed to pump and convey concrete at a job site, but which do not carry the wet mix concrete to the job site, would be included in the definition of cement mixers. Although we are not defining other vehicles as cement mixers, we are allowing miscellaneous vocational vehicles meeting some but not all of the eligibility criteria at 40 CFR 1037.631 to be certified under the custom chassis program, using technology equivalent to the cement mixer package, as described above in Section V.B.

(e) Assigning Vehicles to Subcategories

In the NPRM, the agencies proposed criteria by which a vehicle manufacturer would know in which vocational subcategory—Regional, Urban, or Multipurpose—the vehicle should be certified. These cut-points were defined using calculations relating engine speed to vehicle speed. 80 FR 40287–40288. Specifically, we proposed a cutpoint for the Urban duty cycle where a vehicle at 55 mph would have an engine working above 90 percent of maximum engine test speed for vocational vehicles powered by diesel engines and above 50 percent for vocational vehicles powered by gasoline engines. Similarly, we proposed a cutpoint for the Regional duty cycle where a vehicle at 65 mph would have an engine working below 75 percent of maximum engine test speed

for vocational vehicles powered by diesel engines and below 45 percent for vocational vehicles powered by gasoline engines. We received several comments that identified weaknesses in that approach. Specifically, Allison explained that vehicles with two shift schedules would need clarification which top gear to use when calculating the applicable cut-point. Also, Daimler noted that, to the extent that downspeeding occurs in this sector over the next decade or more, cutpoints based on today's fleet may not be valid for a future fleet. Allison noted that the presence of additional top gears could strongly influence the subcategory placement of vocational vehicles. These comments highlight the possibility of misclassification, and the potential pitfalls in a mandated classification scheme.

Two commenters pointed out important weaknesses in this approach, namely that future trends in engine speeds, torque curves, and transmission gear ratio spreads may cause the vocational fleet of 2027 to have drivelines that are sufficiently different than those of the baseline fleet, so that segment cut-points based on the 2016 fleet may not be valid a decade or more into the future. For example, if data on today's fleet indicated an appropriate cut-point for Regional HHD diesel vehicles of 1,400 rpm engine speed with a vehicle speed of 65 mph, while a future fleet might show that Regional vehicles operated at 1,200 rpm at 65 mph, then having a cut-point set by rule at 1,400 rpm could result in an excess of future vehicles certifying as Regional. However, we have further assessed the impact of manufacturers shifting certification of chassis from Multipurpose to Regional subcategories, and we have concluded this is not an unacceptable outcome. As explained above in Section V.C.(2)(d), we are not particularly concerned that adopting final standards with unequal percent improvements poses a danger of losing environmental benefits from this program, as long as vehicle configurations are properly classified at the time of certification.

In a regulatory structure where baselines are equal but future standards for vehicles in different subcategories have different stringencies, the agencies would typically assign subcategorization based on regulatory criteria rather than allowing the manufacturers unconstrained choice because manufacturers would have a strong incentive to simply choose the least stringent standards. However, because the baseline performance levels of the different vocational vehicle

regulatory subcategories widely differ, the agencies have determined that it is acceptable to adopt standards with unequal percent stringencies. Further discussion of our reasons for this determination is presented above in Section V.C.(2)(d). Another weakness in the proposed approach was that even though we have obtained a great deal of data thanks to manufacturer cooperation and NREL duty cycle analysis, the only one of the proposed regulatory cut-points in which we have a high degree of confidence is the cut-point between Regional and Multipurpose class 8 diesels. Any cut-points we could establish based on available data for lower weight class diesels or for gasoline powered vocational vehicles would be less robust. These weaknesses have led the agencies to take a different approach to assigning vehicles to subcategories. The agencies are adopting final regulations that generally allow manufacturers to choose a subcategory, with a revised set of constraints as well as a provision requiring use of good engineering judgment. The constraints discussed here are being adopted as interim provisions in response to manufacturers' concerns that some of them could present competitive disadvantages, where different manufacturers produce very different sales mixes of vehicles equipped with different transmission types, as discussed above in Section V.C.(2)(d).

Because the baseline configurations against which vehicles in the Urban subcategories will measure their future performance do not include any manual transmissions, we have determined that vocational vehicles with manual transmissions may not be certified as Urban. In the real world, we do not expect any vehicles intended to be used in urban driving patterns will be specified with manual transmissions. Driver fatigue and other performance problems make this an illogical choice of transmission, and thus it is appropriate for us to adopt this constraint. As described in Chapter 2.9.2 of the RIA, both the HHD Regional and HHD Multipurpose baselines have a blend of manual transmissions, although the majority of manuals are in the HHD Regional baseline. Further, by MY 2024, our adoption rate of transmission technology reflects zero manuals in HHD Multipurpose. Thus, beginning in MY 2024, any vocational vehicle certified with a manual transmission must be classified in a Regional subcategory, except a vehicle with a hybridized manual transmission may be certified in a Multipurpose subcategory beyond MY 2024.

We are not adopting constraints on vehicles with automated manual transmissions certifying in either Regional or Multipurpose subcategories, because we believe this is a technology that can provide real world benefits for vehicles with those driving patterns. However, we are adopting an interim constraint to prevent vehicles with AMT from being certified as Urban for a reason similar to one described above for manuals, namely that in the real world, we do not expect any vehicles intended to be used in urban driving patterns will be specified with transmissions that do not have powershifts. Lack of smooth shifting characteristics during low speed accelerations and decelerations make AMT an illogical choice of transmission for urban vehicles, and thus it is appropriate for us to adopt this constraint.

Dual clutch transmissions have very recently become available for medium heavy-duty vocational vehicles and very little data are available on their design or performance. We anticipate that in the future, some designs may have features that make them perform similarly to AMT's while others may have features that make them more similar to automatics with torque converters. Because we are not confident that we know in which duty cycle(s) they are best suited, we are adopting a partial constraint on these, namely that dual clutch transmissions without powershifting must also be constrained out of Urban. We are finalizing as proposed that any vehicle whose engine is exclusively certified over the SET must be certified in the Regional subcategory. Further, to the extent manufacturers of intercity coach buses and recreational vehicles certify these to the primary standards, these also must be certified as Regional vehicles.⁴⁵³

In the final regulatory structure, although the standards for vehicles in different subcategories have different percent stringencies from each baseline, the agencies can allow the manufacturers to choose without risking a loss of environmental benefits because a standard that may appear less stringent in terms of relative improvement from each respective baseline may also be numerically lower (and farther away from current model

performance) due to a comparatively better-performing regulatory baseline. As explained above, the final standards described above in Section V.C.(2)(c) are derived directly from the technology packages without applying any assumptions about fleet averages. Thus, unlike at proposal, the final regulations will generally allow manufacturers to certify in the particular duty-cycle subcategory they believe to be most appropriate. Manufacturers may make this choice as part of the certification process and will not be allowed to change it after the vehicle has been introduced into commerce. Under this structure, the agencies expect manufacturers to choose a subcategory for each vehicle configuration that best represents the type of operation that vehicle will actually experience in use (presuming the manufacturer and customer would specify the technologies to reflect such operation).

(2) Other Compliance Provisions

(a) Emission Control Labels

As proposed, EPA is removing the requirement to include the emission control system identifiers required in 40 CFR 1037.135(c)(6) and in Appendix III to 40 CFR part 1037 from the emission control labels for vehicles certified to the Phase 2 standards. For vehicles certified to the optional custom chassis standards, the label should meet the requirements of 40 CFR 1037.105(h). Please see Section I.C.(1)(g) of this Preamble for additional discussion of labeling.

(b) End of Year Reports

In the Phase 1 program, manufacturers participating in the ABT program provided 90 day and 270 day reports to EPA and NHTSA after the end of the model year. The agencies adopted two reports for the initial program to help manufacturers become familiar with the reporting process. For the HD Phase 2 program, the agencies proposed to simplify reporting such that manufacturers would only be required to submit the final report 90 days after the end of the model year with the potential to obtain approval for a delay up to 30 days. We requested comments on this approach. EMA, PACCAR, Navistar, Daimler, and Cummins recommended keeping the 270 day report to allow sufficient time after the production period is completed. We are accordingly keeping both the 90 day and 270 day reports, with the ability of the agencies' to waive the 90 day report.

(c) Delegated Assembly

The final standards for vocational vehicles are based on the application of

a wide range of technologies. Certifying vehicle manufacturers manage their compliance demonstration to reflect this range of technologies by describing their certified configurations in the application for certification. In most cases, these technologies are designed and assembled (or installed) directly by the certifying vehicle manufacturer, which is typically the chassis manufacturer. In these cases, it is straightforward to assign the responsibility to the certifying vehicle manufacturer for ensuring that vehicles are in their proper certified configuration before they are introduced into commerce. In Phase 1, the only vehicle technology available for certified vocational vehicles is LRR tires. Because these are generally installed by the chassis manufacturer, there is no need to rely on a second stage manufacturer for purposes of certification in Phase 1, unless innovative credits are sought. Thus, the Phase 1 regulations did not specify precise procedures for this.

In Phase 2, the agencies are projecting adoption of certain technologies where the certifying vehicle manufacturer may want or need to rely on a downstream manufacturing company (a secondary vehicle manufacturer) to take steps to assemble or install certain components or technologies to bring the vehicle into a certified configuration. A similar relationship between manufacturers applies with aftertreatment devices for certified engines. EPA previously adopted "delegated assembly" provisions for engines at 40 CFR 1068.261 to describe how manufacturers can share compliance responsibilities through these cooperative assembly procedures, and proposed to also apply it for vehicle-based GHG standards in 40 CFR part 1037, including the vocational vehicle standards.

The delegated assembly provisions being finalized for Phase 2 vehicle standards are only invoked if a certifying manufacturer includes in its certified configuration a technology that it does not install itself. Examples may include fairings to reduce aerodynamic drag, air conditioning systems, automatic tire inflation systems, or hybrid systems. We are clarifying this regulatory process to enable manufacturers to include technologies in their compliance plans that might otherwise not be considered on the basis of what they can install themselves. To the extent certifying manufacturers rely on secondary vehicle manufacturers to bring the vehicle into a certified configuration, the following provisions will apply:

⁴⁵³ Based on NREL drive cycle analysis of the existing fleet, we imagine that HHD vehicles with a diesel engine rpm of 1,400 and below when the vehicle is at 65 mph would be appropriately certified as Regional vehicles. However, this is illustrative only, and the final rules do not include an engine speed cutpoint as a criterion in subcategory selection.

- The certifying manufacturer will describe its approach to delegated assembly in the application for certification.
- The certifying manufacturer will create installation instructions to describe how the secondary vehicle manufacturer will bring the vehicle into a certified configuration.
- The certifying manufacturer must take additional steps for certified configurations that include hybrid powertrain components, auxiliary power units, aerodynamic devices, or natural gas fuel tanks. In these cases, the certifying manufacturer must have a contractual agreement with each affected secondary vehicle manufacturer obligating the secondary vehicle manufacturer to build each vehicle into a certified configuration and to provide affidavits confirming proper assembly procedures, and to provide information regarding deployment of each type of technology (if there are technology options that relate to different GEM input values).

See Section I.F of this Preamble and Section 1.4.4 of the RTC for further discussion of the comments received on delegated assembly provisions.

The agencies have developed the delegated-assembly and other provisions in 40 CFR 1037.620—1037.622 to clarify how manufacturers have shared and separate responsibilities for complying with the regulations. Vocational vehicles are the most likely vehicle types to involve both primary and secondary manufacturers; however, other types of vehicles may also involve multiple manufacturers, so these regulatory provisions apply to all vehicles.

Secondary manufacturers (such as body builders) that build complete vehicles from certified chassis are obligated to comply with the emission-related installation instructions provided by the certifying manufacturer. Secondary manufacturers that build complete vehicles from exempted chassis are similarly obligated to comply with all of the regulatory provisions related to the exemption.

(d) Demonstrating Compliance With HFC Leakage Standards

EPA's requirements for vocational chassis manufacturers to demonstrate reductions in direct emissions of HFC in their A/C systems and components through a design-based method. The method for calculating A/C leakage is the same as was adopted in Phase 1 for tractors and HD pickups and vans. It is based closely on an industry-consensus leakage scoring method, described below. This leakage scoring method is

correlated to experimentally-measured leakage rates from a number of vehicles using the different available A/C components. As is done currently for other HD vehicles, vocational chassis manufacturers will choose from a menu of A/C equipment and components used in their vehicles in order to establish leakage scores, to characterize their A/C system leakage performance. The percent leakage per year will then be calculated as this score divided by the system refrigerant capacity. We received comments from transit bus manufacturers with concerns that the air conditioning systems on their vehicles are much larger and more complex than systems on typical heavy-duty trucks. As such, they questioned whether our HFC leakage compliance process was valid for their vehicles. Based on information provided by suppliers of air conditioning systems for large buses, we believe some unusually large systems may include components not adequately represented by those listed in the standard compliance procedure, namely the hoses, fittings or seals may not be listed with realistic leakage rates. Therefore EPA is adopting in this final rule provisions allowing use of an alternate compliance procedure where an air conditioning system with refrigerant charge capacity greater than 3,000 grams is installed in a Phase 2 vocational vehicle.

Consistent with the light-duty rule and the Phase 1 program for other HD vehicles, vocational chassis manufacturers will compare the components of a vehicle's A/C system with a set of leakage-reduction technologies and actions that is based closely on that developed through the Improved Mobile Air Conditioning program and SAE International (as SAE Surface Vehicle Standard J2727, "HFC-134a, Mobile Air Conditioning System Refrigerant Emission Chart," August 2008 version). See generally 75 FR 25426. The SAE J2727 approach was developed from laboratory testing of a variety of A/C related components, and EPA believes that the J2727 leakage scoring system generally represents a reasonable correlation with average real-world leakage in new vehicles. This approach associates each component with a specific leakage rate in grams per year that is identical to the values in J2727 and then sums together the component leakage values to develop the total A/C system leakage. Unlike the light-duty program, in the heavy-duty vehicle program, the total A/C leakage score is divided by the value of the total refrigerant system capacity to develop a percent leakage per year.

EPA concludes that the design-based approach results in estimates of likely leakage emissions reductions that are comparable to those that would result from performance-based testing. Where a manufacturer installs an air conditioning system in a vocational vehicle that has a working fluid consisting of an alternate refrigerant with a lower global warming potential than HFC-134a, compliance with the leakage standard is addressed in the regulations at 40 CFR 1037.115. Please see Section I.F.(2)(b) for a discussion related to alternative refrigerants.

Consistent with the HD Phase 1 program and the light-duty rule, where we require that manufacturers attest to the durability of components and systems used to meet the CO₂ standards (see 75 FR 25689), we are requiring that manufacturers of heavy-duty vocational vehicles attest to the durability of these systems, and provide an engineering analysis that demonstrates component and system durability.

(e) Glider Vehicles

EPA and NHTSA requested comment on gliders and received extensive comment. The main issues involve standards for rebuilt engines installed in new glider vehicles. These issues are fully addressed in Preamble Section XIII.B and RTC Section 14.2. Of relevance for the vocational vehicle sector, the final standards contain a number of provisions allowing donor engines that are still within their regulatory useful life to be used in new glider vehicles provided the engine meets all standards applicable to the year in which the engine was originally manufactured and also meets one of the following criteria:

- The engine is still within its original useful life in terms of both miles and years.
- The engine has less than 100,000 miles of engine operation.
- The engine is less than three years old.

Thus, if a donor engine meeting one of the above criteria was manufactured before the Phase 1 GHG standards, it would not be subject to those standards when installed in a glider vehicle. Similarly, if such an engine was manufactured before 2010, it would be subject to the pre-2010 criteria pollutant standards corresponding to its year of manufacture. EPA is adopting this provision consistent with the original purpose of glider vehicles as providing a means of salvaging of relatively new powertrains from vehicle chassis that have been damaged or have otherwise failed prematurely. See Section XIII.B of the Preamble.

(3) Compliance Flexibility Provisions

EPA and NHTSA are adopting several flexibility provisions in the Phase 2 program. Program-wide compliance flexibilities include an averaging, banking and trading program for CO₂ emissions and fuel consumption credits, provisions for off-cycle credits for technologies that are not included as inputs to the GEM, and advanced technology credits. These are described below as well as in Section I.B.3 to I.C.1. Provisions that are not program-wide include optional chassis certification and a revised interim loose engines provision, as described below.

(a) Averaging, Banking, and Trading (ABT) Program

Averaging, banking, and trading of emission credits have been an important part of many EPA mobile source programs under CAA Title II. ABT provisions provide manufacturers flexibilities that assist in the efficient development and implementation of new technologies and therefore enable new technologies to be implemented at a more aggressive pace than without ABT. NHTSA and EPA are carrying-over the Phase 1 ABT provisions for vocational vehicles into Phase 2, as it is an important way to achieve each agency's programmatic goals. ABT is also discussed in Section I and Section III.F.1.

Consistent with the Phase 1 averaging sets, the agencies are allowing chassis manufacturers to average SI-powered vocational vehicle chassis with CI-powered vocational vehicle chassis, within the same vehicle weight class group. In Phase 1, all vocational and tractor chassis within a vehicle weight class group were able to average with each other, regardless of whether they were powered by a CI or SI engine. The Phase 2 approach continues this. The only difference is that in Phase 2, there are different numerical standards set for the SI-powered and CI-powered vehicles, but that does not alter the basis for averaging. This is consistent with the Phase 1 approach where, for example, Class 8 day cab tractors, Class 8 sleeper cab tractors and Class 8 vocational vehicles each have different numerical standards, while they all belong to the same averaging set.

As discussed in V.D.(1)(c), EPA and NHTSA are adopting a revised useful life for LHD vocational vehicles for GHG emissions from the current 10 years/110,000 miles to 15 years/150,000 miles, to be consistent with the useful life of criteria pollutants recently updated in EPA's Tier 3 rule. For the same reasons, EPA and NHTSA are also adopting a

useful life adjustment for HD pickups and vans, as described in Section V.I.E.(1). According to the credits calculation formula at 40 CFR 1037.705 and 49 CFR 535.7, useful life in miles is a multiplicative factor included in the calculation of CO₂ and fuel consumption credits. In order to ensure that banked credits will maintain their value in the transition from Phase 1 to Phase 2, NHTSA and EPA are adopting an interim vocational vehicle adjustment factor of 1.36 for credits that are carried forward from Phase 1 to the MY 2021 and later Phase 2 standards.⁴⁵⁴ Without this adjustment factor the change in useful life would effectively result in a discount of banked credits that are carried forward from Phase 1 to Phase 2, which is not the intent of the change in the useful life. The agencies do not believe that this adjustment will result in a loss of program benefits because there is little or no deterioration anticipated for CO₂ emissions and fuel consumption over the life of the vehicles. Also, the carry-forward of credits is an integral part of the program, helping to smooth the transition to the Phase 2 standards. The agencies believe that effectively discounting carry-forward credits from Phase 1 to Phase 2 is unnecessary and could negatively impact the feasibility of the Phase 2 standards. EPA and NHTSA requested comment on all aspects of the averaging, banking, and trading program. A complete discussion of the comments on credits and ABT can be found in the RTC Section 1.4.

(b) Innovative and Off-Cycle Technology Credits

In Phase 1, the agencies adopted an emissions and fuel consumption credit generating opportunity that applied to innovative technologies that reduce fuel consumption and CO₂ emissions. Eligible technologies were required to not be in common use with heavy-duty vehicles before the 2010MY and not reflected in the GEM simulation tool (*i.e.*, the benefits are "off-cycle"). See 76 FR 57253. In Phase 2, the agencies are re-designating it as an off-cycle technology program. The agencies are maintaining the requirement that, in order for a manufacturer to receive credits for Phase 2, the off-cycle technology must not have been in common use prior to MY 2010.

The agencies recognize that there are emerging technologies today that are being developed, but will not be accounted for in the GEM tool, and therefore will be considered off-cycle. For vocational vehicles, this could

include technologies whose scope and effectiveness surpass those defined and pre-approved in the HD Phase 2 program, such as aerodynamics and electrified accessories. Any credits for these technologies will need to be based on real-world fuel consumption and GHG reductions that can be measured with verifiable test methods using representative driving conditions typical of the engine or vehicle application. More information about off-cycle technology credits can be found at Section I.C.1.c.

As in Phase 1, the agencies will continue to provide two paths for approval of the test procedure to measure the CO₂ emissions and fuel consumption reductions of an off-cycle technology used in vocational vehicles. See 40 CFR 1037.610 and 49 CFR 535.7. The first path will not require a public approval process of the test method. A manufacturer may use "pre-approved" test methods for HD vehicles including the A-to-B chassis testing, powerpack testing or on-road testing. A manufacturer may also use any developed test procedure that has known quantifiable benefits. A test plan detailing the testing methodology will be required to be approved prior to collecting any test data. The agencies are also continuing the second path, which includes a public approval process of any testing method that could have questionable benefits (*i.e.*, an unknown usage rate for a technology). Furthermore, the agencies are adopting revisions to clarify what documentation must be submitted for approval, aligning them with provisions in 40 CFR 86.1869–12. NHTSA is prohibiting credits from technologies addressed by any of its crash avoidance safety rulemakings (*i.e.*, congestion management systems). See also 77 FR 62733 (discussion of similar issue in the light duty greenhouse gas/fuel economy regulations). We received extensive comment on the off-cycle technology approval process. In response to requests to develop a streamlined path for off-cycle technology approval, we are not making fundamental changes from the proposal at this time; however, we remain open to working with stakeholders to look for ways to simplify the process. For example, although we are including specific provisions to recognize certain electrified accessories, recognizing others would require the manufacturer to go through the off-cycle process. However, it is quite possible that the agencies could gather sufficient data to allow us to adopt specific provisions in a future rulemaking to recognize other accessories in a simpler

⁴⁵⁴ See 40 CFR 1037.150(o) and 49 CFR 535.7.

manner. Please see Section I.C. of this Preamble for further discussion of off-cycle credits.

There are some technologies that are entering the market today, and although our model does not have the capability to simulate the effectiveness over the test cycles, there are reliable estimates of effectiveness available to the agencies. These will be recognized in our HD Phase 2 certification procedures as pre-defined technologies, and will not be considered off-cycle. Examples of such technologies for vocational vehicles include narrowly-defined types of electrified accessories or aerodynamic improvements. The agencies are specifying default effectiveness values to be used as valid inputs to GEM for each of these. The projected effectiveness of each vocational vehicle technology is discussed in the RIA Chapter 2.9.3.

The agencies' approval for Phase 1 innovative technology credits (approved prior to 2021 MY) will be carried into the Phase 2 program on a limited basis for those technologies where the benefit is not accounted for in the Phase 2 test procedure. Therefore, the manufacturers will not be required to request new approval for any innovative credits carried into the off-cycle program, but will have to demonstrate, as part of the MY 2021 certification, the extent to which the new cycle does not account for these improvements. The agencies believe this is appropriate because technologies, such as those related to the transmission or driveline, may no longer be "off-cycle" because of the addition of these technologies into the Phase 2 version of GEM.

(c) Advanced Technology Credits

As described above in Section I, the agencies proposed to discontinue advanced technology credits in Phase 2, which had been intended to promote the early implementation of advanced technologies that were not expected to be widely adopted in the market in the 2014 to 2018 time frame. These technologies were defined in Phase 1 as hybrid powertrains, Rankine cycle engines, all-electric vehicles, and fuel cell vehicles (see 40 CFR 1037.150(p)), at a 1.5 credit value. We requested and received comments on the need for such incentives, and as a result we are not only continuing these credits, we are adopting even greater multipliers than before. See Section I of this Preamble for further discussion of the comments received and the agencies' response regarding advanced technology credits.

(d) Optional Chassis Certification

In Phase 2, the agencies are continuing the Phase 1 option to chassis certify vehicles over 14,000 lbs GVWR, but only if there is a family with vehicles at or below 14,000 pounds GVWR that can properly accommodate the bigger vehicles as part of the same family. As adopted in this final rule, chassis-certified vehicles above 14,000 pounds GVWR may not rely on a work factor that is greater than the largest work factor that applies for vehicles at or below 14,000 pounds GVWR from the same family. Applying this work factor constraint avoids the need to set a specific upper GVWR limit on vehicles eligible to use this flexibility. See Section XIII.A.2 of this Preamble, and Section 14.3.2 of the RTC, for further discussion of this issue.

(e) Certifying Loose SI Engines in Vocational Vehicles in Phase 2

The agencies proposed not to continue the Phase 1 interim flexibility known as the "loose engine" provision, receiving favorable comment from Cummins and adverse comment on this from Isuzu and AAPC. 80 FR 40331. Under this provision, SI engines produced by manufacturers of HD pickup trucks and vans and sold to chassis manufacturers and intended for use in vocational vehicles need not meet the separate SI engine standard, and instead may be averaged with the manufacturer's HD pickup and van fleet (see 40 CFR 86.1819–14(k)(8)). The agencies are adopting a Phase 2 SI engine standard that is no more stringent than the MY 2016 SI engine standard adopted in Phase 1, while the Phase 2 standards for the HD pickup and van fleet is progressively more stringent through MY 2027. The primary certification path designed in the Phase 1 program for both CI and SI engines sold separately and intended for use in vocational vehicles is that they are engine certified while the vehicle is GEM certified under the GHG rules.

This provision was adopted primarily to address small volume sales of engines used in complete vehicles that are also sold to other manufacturers. The Phase 1 final rules explain that we set the effective date of the Phase 1 SI engine standard as MY 2016 because we projected by this time all manufacturers would have redesigned their gasoline engine offerings to adopt the technologies needed to reduce FTP-cycle emissions by five percent; technologies that cannot simply be bolted on to an existing engine but can only be effectively applied through an integrated design and development

process (76 FR 57180, 57235). The Phase 1 final rules also explain that the compliance flexibility provided by the loose engine provision is technically appropriate because it provides manufacturers with an option to focus their energy on improving the GHG and fuel consumption performance of their complete vehicle products (including engine improvements), rather than on concurrently calibrating for both vehicle and engine test compliance (76 FR 57260). At proposal we noted that although gasoline engine manufacturers have accomplished extensive improvements to comply with HD pickup and vans standards as well as the light-duty vehicle standards, the agencies had not seen evidence of the engine redesigns that we had projected to occur by 2016, and we concluded that discontinuation of this flexibility by MY 2021 was appropriate to provide regulatory certainty on the date beyond which engine certification would be mandatory for HD SI engines.

However, in response to persuasive comments from a chassis manufacturer that purchases these engines, we are adopting a narrow extension of this interim flexibility, where for MYs 2021–2023, each SI engine manufacturer may sell an annual maximum of 10,000 SI engines certified under this provision.⁴⁵⁵ We believe this three-year extension is needed to prevent market disruptions. We are concerned that SI engine manufacturers might not choose to certify any SI engines that can be sold to other vocational chassis manufacturers, which would significantly disrupt the market. With this limited extension, we are ensuring no loss of environmental benefits because any vehicle certified by a chassis manufacturer who obtains a high-emitting SI engine must apply additional technology as needed to meet the applicable vocational vehicle standard. We are generally not allowing custom chassis manufacturers to use SI engines that have been certified under this loose engine provision, if they are certifying using one of the custom chassis regulatory subcategories. However, manufacturers certifying motor homes or emergency vehicles to the optional standards may install engines certified through the interim loose engine provision. The typical annual miles driven by these vehicles is very low, usually between 2,000 and 5,000 miles for either motor homes or emergency vehicles, and thus their contribution to emissions and fuel consumption is very small. See Section II of this Preamble for a discussion of

⁴⁵⁵ Meeting with Isuzu dated April 22, 2016.

the comments received and the agencies' response on the separate engine standard for SI engines intended for vocational vehicles.

(f) On-Board Diagnostics for Hybrid Vehicle Systems

In HD Phase 1, EPA adopted provisions to delay the onboard diagnostics (OBD) requirements for heavy-duty hybrid powertrains (see 40 CFR 86.010–18(q)). This provision delayed full OBD requirements for hybrids until MY 2016 and MY 2017. The agencies have received comments from hybrid manufacturers regarding their progress toward meeting the on-board diagnostic requirements for criteria pollutant engine certification related to hybrid systems. See Section XIII.A.1 for a discussion of comments received and EPA's response related to certification of engines paired with hybrid powertrain systems.

VI. Heavy-Duty Pickups and Vans

In the NPRM, the agencies conducted coordinated and complementary analyses using two analytical methods for the heavy-duty pickup and van segment, both of which used the same version of NHTSA's CAFE model to analyze technology. The agencies have also used two analytical methods for the joint final rule. However, unlike the NPRM, for the joint final rule, the agencies are using different versions of NHTSA's CAFE model to analyze technology. The Method B approach continues to use the same version of the model and inputs that was used for the NPRM. Method A uses an updated version of the CAFE model and some updated inputs.

A. Summary of Phase 1 HD Pickup and Van Standards

In the Phase 1 rule, EPA and NHTSA established GHG and fuel consumption standards and a program structure for complete Class 2b and 3 heavy-duty vehicles (referred to in these rules as "HD pickups and vans"), as described below. The Phase 1 standards began to be phased-in in MY 2014 and the agencies believe the program is working well. The agencies are retaining most elements from the structure of the program established in the Phase 1 rule for the Phase 2 program while establishing more stringent Phase 2 standards for MY 2027, phased in over MYs 2021–2027, that will require additional GHG reductions and fuel consumption improvements. As discussed below, the agencies are adopting the Phase 2 standards as proposed. The MY 2027 standards will

remain in place unless and until amended by the agencies.

Heavy-duty vehicles with GVWR between 8,501 and 10,000 lbs. are classified in the industry as Class 2b motor vehicles. Class 2b includes vehicles classified as medium-duty passenger vehicles (MDPVs) such as very large SUVs. Because MDPVs are frequently used like light-duty passenger vehicles, they are regulated by the agencies under the light-duty vehicle rules. Thus, the agencies did not adopt additional requirements for MDPVs in the Phase 1 rule and are not adopting additional requirements for MDPVs in this rulemaking. Heavy-duty vehicles with GVWR between 10,001 and 14,000 lbs are classified as Class 3 motor vehicles. Class 2b and Class 3 heavy-duty vehicles together emit about 23 percent of today's GHG emissions from the heavy-duty vehicle sector.

About 90 percent of HD pickups and vans are $\frac{3}{4}$ -ton and 1-ton pickup trucks, 12- and 15-passenger vans, and large work vans that are sold by vehicle manufacturers as complete vehicles, with no secondary manufacturer making substantial modifications prior to registration and use. Most of these vehicles are produced by companies with major light-duty markets in the United States, primarily Ford, General Motors, and Fiat Chrysler. Often, the technologies available to reduce fuel consumption and GHG emissions from this segment are similar to the technologies used for the same purpose on light-duty pickup trucks and vans, including both engine efficiency improvements (for gasoline and diesel engines) and vehicle efficiency improvements.

In the Phase 1 rule, EPA adopted GHG standards for HD pickups and vans based on the whole vehicle (including the engine), expressed as grams of CO₂ per mile, consistent with the way these vehicles are regulated by EPA today for criteria pollutants. NHTSA adopted corresponding gallons per 100 mile fuel consumption standards that are likewise based on the whole vehicle. This complete vehicle approach adopted by both agencies for HD pickups and vans was consistent with the recommendations of the NAS Committee in its 2010 Report. EPA and NHTSA adopted a structure for the Phase 1 HD pickup and van standards that in many respects paralleled long-standing NHTSA CAFE standards and more recent coordinated EPA GHG standards for manufacturers' fleets of new light-duty vehicles. These commonalities include a new vehicle fleet average standard for each manufacturer in each model year and

the determination of these fleet average standards based on production volume-weighted targets for each model, with the targets varying based on a defined vehicle attribute. Vehicle testing for both the HD and light-duty vehicle programs is conducted on chassis dynamometers using the drive cycles from the EPA Federal Test Procedure (Light-duty FTP or "city" test) and Highway Fuel Economy Test (HFET or "highway" test).⁴⁵⁶

For the light-duty GHG and fuel economy⁴⁵⁷ standards, the agencies factored in vehicle size by basing the emissions and fuel economy targets on vehicle footprint (the wheelbase times the average track width).⁴⁵⁸ For those standards, passenger cars and light trucks with larger footprints are assigned higher GHG and lower fuel economy target levels in acknowledgement of their inherent tendency to consume more fuel and emit more GHGs per mile. EISA requires that NHTSA study "the appropriate metric for measuring and expressing commercial medium- and heavy-duty vehicle and work truck fuel efficiency performance, taking into consideration, among other things, the work performed by such on-highway vehicles and work trucks . . ." See 49 U.S.C. 32902(k)(1)(B).⁴⁵⁹ For HD pickups and vans, the agencies also set standards based on a vehicle attribute, but used a work-based metric as the attribute rather than the footprint attribute utilized in the light-duty vehicle rulemaking. Work-based measures such as payload and towing capability are key among the parameters that characterize differences in the design of these vehicles, as well as differences in how the vehicles will be utilized. Buyers consider these utility-based attributes when purchasing a HD pickup or van. EPA and NHTSA therefore finalized Phase 1 standards for HD pickups and vans based on a "work factor" attribute that combines the vehicle's payload and towing capabilities, with an added adjustment

⁴⁵⁶ The Light-duty FTP is a vehicle driving cycle that was originally developed for certifying light-duty vehicles and subsequently applied to HD chassis testing for criteria pollutants. This contrasts with the Heavy-duty FTP, which refers to the transient engine test cycles used for certifying heavy-duty engines (with separate cycles specified for diesel and spark-ignition engines).

⁴⁵⁷ Light duty fuel economy standards are expressed as miles per gallon (mpg), which is inverse to the HD fuel consumption standards which are expressed as gallons per 100 miles.

⁴⁵⁸ EISA requires CAFE standards for passenger cars and light trucks to be attribute-based; See 49 U.S.C. 32902(b)(3)(A).

⁴⁵⁹ The NAS 2010 report likewise recommended standards recognizing the work function of HD vehicles. See 76 FR 57161.

for 4-wheel drive vehicles. See generally 76 FR 57161–57162.

For Phase 1, the agencies adopted provisions such that each manufacturer's fleet average standard is based on production volume-weighting of target standards for all vehicles that in turn are based on each vehicle's work factor. These target standards are taken

from a set of curves (mathematical functions). The Phase 1 curves are shown in the figures below for reference and are described in detail in the Phase 1 final rule.⁴⁶⁰ The agencies established separate curves for diesel and gasoline HD pickups and vans. The agencies will continue to use the work-based attribute and gradually declining standards

approach for the Phase 2 standards, as discussed in Section VI.B. below. Note that this approach does not create an incentive to reduce the capabilities of these vehicles because less capable vehicles are required to have proportionally lower emissions and fuel consumption targets.

Figure VI-1 EPA Phase 1 CO₂ Target Standards and NHTSA Fuel Consumption Target Standards for Diesel HD Pickups and Vans⁴⁶¹

⁴⁶⁰ The Phase 1 Final Rule provides a full discussion of the standard curves including the equations and coefficients. See 76 FR 57162–57165, September 15 2011. The standards were previously provided in the regulations at 40 CFR 1037.104, but

they are now being redesignated as 40 CFR 86.1819–14.

⁴⁶¹ The NHTSA program provides voluntary standards for model years 2014 and 2015. Target

line functions for 2016–2018 are for the second NHTSA alternative described in the Phase 1 Preamble Section II.C.(d)(ii).

Figure VI-2 EPA Phase 1 CO₂ Target Standards and NHTSA Fuel Consumption Target Standards for Gasoline HD Pickups and Vans

EPA phased in its CO₂ standards gradually starting in the 2014 model year, at 15–20–40–60–100 percent of the model year 2018 standards stringency level in model years 2014–2015–2016–2017–2018, respectively. The phase-in takes the form of the set of target standard curves shown above, with increasing stringency in each model year. The final EPA Phase 1 standards for 2018 (including a separate standard to control air conditioning system leakage) represent an average per-vehicle reduction in GHGs of 17 percent for diesel vehicles and 12 percent for gasoline vehicles, compared to a common MY 2010 baseline. EPA also finalized a compliance alternative whereby manufacturers can phase in different percentages: 15–20–67–67–67–100 percent of the model year 2019 standards stringency level in model years 2014–2015–2016–2017–2018–

2019, respectively. This compliance alternative parallels and is equivalent to NHTSA's first alternative described below.

NHTSA's Phase 1 program allows manufacturers to select one of two fuel consumption standard alternatives for model years 2016 and later. The first alternative defines individual gasoline vehicle and diesel vehicle fuel consumption target curves that will not change for model years 2016–2018, and are equivalent to EPA's 67–67–67–100 percent target curves in model years 2016–2017–2018–2019, respectively. This option is consistent with EISA requirements that NHTSA provide 4 years lead-time and 3 years of stability for standards. See 49 U.S.C. 32902(k)(3). The second alternative uses target curves that are equivalent to EPA's 40–60–100 percent target curves in model years 2016–2017–2018, respectively.

This option is also consistent with EISA lead-time and stability requirements. Stringency for the alternatives in Phase 1 was selected by the agencies to allow a manufacturer, through the use of the credit carry-forward and carry-back provisions that the agencies also finalized, to meet both NHTSA fuel efficiency and EPA GHG emission standards using a single compliance strategy. If a manufacturer cannot meet an applicable standard in a given model year, it may make up its shortfall by over-complying in a subsequent year. NHTSA also allows manufacturers to voluntarily opt into the NHTSA HD pickup and van program in model years 2014 or 2015. For these model years, NHTSA's fuel consumption target curves are equivalent to EPA's target curves. The Phase 1 phase-in options are summarized in Table VI–1.

TABLE VI–1—PHASE 1 STANDARDS PHASE-IN OPTIONS

	2014 %	2015 %	2016 %	2017 %	2018 %	2019 %
EPA Primary Phase-in	15	20	40	60	100	100
EPA Compliance Option	15	20	67	67	67	100

TABLE VI-1—PHASE 1 STANDARDS PHASE-IN OPTIONS—Continued

	2014 %	2015 %	2016 %	2017 %	2018 %	2019 %
NHTSA First Option	0	0	67	67	67	100
NHTSA Second Option	0	0	40	60	100	100

The form and stringency of the Phase 1 standards curves are based on the performance of a set of vehicle, engine, and transmission technologies expected (although not required) to be used to meet the GHG emissions and fuel economy standards for model year 2012–2016 light-duty vehicles, with full consideration of how these technologies are likely to perform in heavy-duty vehicle testing and use. All of these technologies are already in use or have been announced for upcoming model years in some light-duty vehicle models, and some are in use in a portion of HD pickups and vans as well. The technologies include:

- advanced 8-speed automatic transmissions
- aerodynamic improvements
- electro-hydraulic power steering
- engine friction reductions
- improved accessories
- low friction lubricants in powertrain components
- lower rolling resistance tires
- lightweighting
- gasoline direct injection
- diesel aftertreatment optimization
- air conditioning system leakage reduction (for EPA program only)

B. HD Pickup and Van Final Phase 2 Standards

As described in this section, NHTSA and EPA are adopting as proposed Phase 2 standards that will be phased in over model years 2021–2027 and continue thereafter unless and until amended. These standards are identical to those proposed as Alternative 3 (the preferred alternative at proposal). The agencies are adopting standards based on a year-over-year increase in stringency of 2.5 percent over MYs 2021–2027 for a total increase in stringency for the Phase 2 program of about 16 percent compared to the MY 2018 Phase 1 standard. Note that an individual manufacturer's fleet-wide target may differ from this stringency increase due to changes in vehicle sales mix and changes in work factor. We believe the standards the agencies are adopting are feasible in the time frame of this rule.

As discussed in detail below in Sections C through F, the agencies performed separate analyses, which we refer to as “Method A” and “Method B.”

NHTSA considered Method A as the central analysis in its determination of the stringency of the Phase 2 standards. EPA considered the results of Method B as the central analysis for its determination of the stringency of the Phase 2 standards. These analyses are complementary, and independently support the same conclusion.

In the proposal, the agencies also sought comment on a number of alternatives, including an alternative (‘Alternative 4’) which would have resulted in approximately the same stringency increase, but would have done so two years earlier (in MY 2025 rather than MY 2027), so that the effective year-over-year stringency would have been 3.5%. The agencies are not adopting this alternative. The agencies' analyses show that the additional lead-time provided by the Phase 2 standards that the agencies are adopting will allow manufacturers to more fully utilize lower cost technologies over vehicle life-cycles. In addition, under the method B analysis, this would reduce the projected adoption rate of more advanced higher cost technologies such as strong hybrids compared to Alternative 4. As discussed in more detail in E.1 below, both of the considered phase-ins are projected to require comparable penetration rates of several non-hybrid technologies with some approaching 100 percent penetration. However, as discussed below, the additional lead-time provided by the final standards will allow manufacturers more flexibility to implement technologies at later redesigns and refreshes. The agencies received several comments regarding the timing and stringency of the standards. These comments are discussed in detail in Section E.1 below and in Chapter 7 of the Response to Comments document.

When considering potential Phase 2 standards, the agencies anticipate that the technologies listed above that were considered in Phase 1 will continue to be available in the future, if not already applied under Phase 1 standards, and that additional technologies will also be available:

- advanced engine improvements for friction reduction and low friction lubricants

- improved engine parasitics, including fuel pumps, oil pumps, and coolant pumps
- valvetrain variable lift and timing
- cylinder deactivation
- direct gasoline injection
- cooled exhaust gas recirculation
- turbo downsizing of gasoline engines
- Diesel engine efficiency improvements
- downsizing of diesel engines
- 8-speed automatic transmissions
- electric power steering
- high efficiency transmission gear boxes and driveline
- further improvements in accessory loads
- additional improvements in aerodynamics and tire rolling resistance
- low drag brakes
- mass reduction
- mild hybridization
- strong hybridization

Sections VI.C below and Section 2 of the RIA provide a detailed analysis of these and other potential technologies for Phase 2, including their feasibility, costs, and effectiveness and projected application rates for reducing fuel consumption and CO₂ emissions when utilized in HD pickups and vans. Sections VI.D and Section X also discuss the selection of the Phase 2 standards and the alternatives considered.

In addition to EPA's CO₂ emission standards and NHTSA's fuel consumption standards for HD pickups and vans, EPA in Phase 1 also finalized standards for two additional GHGs—N₂O and CH₄, as well as standards for air conditioning-related HFC emissions. EPA will continue these standards in Phase 2. Also, consistent with CAA section 202(a)(1), EPA finalized Phase 1 standards that apply to HD pickups and vans in use and EPA is likewise adopting in-use standards for these vehicles in Phase 2. All of these standards are discussed in more detail below. Program flexibilities and compliance provisions related to the standards for HD pickups and vans are discussed in Section VI.E.

A relatively small number of HD pickups and vans are sold by vehicle manufacturers as incomplete vehicles, without the primary load-carrying device or container attached. A sizeable

subset of these incomplete vehicles, often called cab-chassis vehicles, are sold by the vehicle manufacturers in configurations with complete cabs plus many of the components that affect GHG emissions and fuel consumption identical to those on complete pickup truck or van counterparts—including engines, cabs, frames, transmissions, axles, and wheels. The Phase 1 program includes provisions that allow manufacturers to include these incomplete vehicles, as well as some Class 4 through 6 vehicles, to be regulated under the chassis-based HD pickup and van program (*i.e.* subject to the standards and chassis certification for HD pickups and vans), rather than under the vocational vehicle program.⁴⁶² The agencies are continuing to allow such incomplete vehicles the option of certifying under either the heavy duty pickup and van standards or the standards for vocational vehicles. As in Phase 1, if such an incomplete vehicle is certified as a vocational vehicle, the engine would have to be certified separately to the applicable engine standard.

Phase 1 also includes optional compliance paths for spark-ignition engines identical to engines used in heavy-duty pickups and vans to comply with 2b/3 standards. See 40 CFR 1037.150(m) and 49 CFR 535.5(a)(7). Manufacturers sell such engines as “loose engines” or install these engines in incomplete vehicles that are not cab-complete vehicles. The agencies are providing a temporary loose engine provision for Phase 2 as described in Section V.D.3.e, under Compliance Flexibility Provisions. These program elements are discussed above in Section V.D. on vocational vehicles and XIII.A.2 on engines.

(1) Vehicle-Based Standards

For Phase 1, EPA and NHTSA chose to set vehicle-based standards whereby the entire vehicle is chassis-tested. The agencies will retain this approach for Phase 2. About 90 percent of Class 2b and 3 vehicles are pickup trucks, passenger vans, and work vans that are sold by the original equipment manufacturers as complete vehicles, ready for use on the road. In addition, most of these complete HD pickups and vans are covered by CAA vehicle emissions standards for criteria pollutants (*i.e.*, they are chassis tested similar to light-duty), expressed in grams per mile. This distinguishes this category from other, larger heavy-duty vehicles that typically have engines

covered by CAA engine emission standards for criteria pollutants, expressed in grams per brake horsepower-hour. As a result, Class 2b and 3 complete vehicles share both substantive elements and a regulatory structure much more in common with light-duty trucks than with the other heavy-duty vehicles.

Three of these features in common are especially significant: (1) Over 95 percent of the HD pickups and vans sold in the United States are produced by Ford, General Motors, and Fiat Chrysler—three companies with large light-duty vehicle and light-duty truck sales in the United States; (2) these companies typically base their HD pickup and van designs on higher sales volume light-duty truck platforms and technologies, often incorporating new light-duty truck design features into HD pickups and vans at their next design cycle, and (3) at this time most complete HD pickups and vans are certified to vehicle-based rather than engine-based EPA criteria pollutant and GHG standards. There is also the potential for substantial GHG and fuel consumption reductions from vehicle design improvements beyond engine changes (such as through optimizing aerodynamics, weight, tires, and accessories), and a single manufacturer is generally responsible for both engine and vehicle design. All of these factors together suggest that it is still appropriate and reasonable to base standards on performance of the vehicle as a whole, rather than to establish separate engine and vehicle GHG and fuel consumption standards, as is being done for the other heavy-duty categories. The chassis-based standards approach for complete vehicles is also consistent with NAS⁴⁶³ recommendations and there was consensus in the public comments in the Phase 1 rulemaking supporting this approach. For all of these reasons, the agencies proposed to continue this approach, and there was again supporting consensus in the public comments.

(a) Work-Based Attributes

In developing the Phase 1 HD rulemaking, the agencies emphasized creating a program structure that achieves reductions in fuel consumption and GHGs based on how vehicles are used and on the work they perform in the real world. Work-based measures such as payload and towing capability are key among the things that characterize differences in the design of vehicles, as well as differences in how

the vehicles will be used. Vehicles in the 2b and 3 categories have a wide range of payload and towing capacities. These work-based differences in design and in-use operation are key factors in evaluating technological improvements for reducing CO₂ emissions and fuel consumption. Payload has a particularly important impact on the test results for HD pickup and van emissions and fuel consumption, because testing under existing EPA procedures for criteria pollutants and the Phase 1 standards is conducted with the vehicle loaded to half of its payload capacity (rather than to a flat 300 lbs. as in the light-duty program), and the correlation between test weight and fuel use is strong.

Towing, on the other hand, does not directly factor into test weight as nothing is towed during the test. Hence, setting aside any interdependence between towing capacity and payload, only the higher curb weight caused by any heavier truck components plays a role in affecting measured test results. However towing capacity can be a significant factor to consider because HD pickup truck towing capacities can be quite large, with a correspondingly large effect on vehicle design.

We note too that, from a purchaser perspective, payload and towing capability typically play a greater role than physical dimensions in influencing purchaser decisions on which heavy-duty vehicle to buy. For passenger vans, seating capacity is of course a major consideration, but this correlates closely with payload weight.

For these reasons, as noted above, EPA and NHTSA set Phase 1 standards for HD pickups and vans based on a “work factor” attribute that combines vehicle payload capacity and vehicle towing capacity, in lbs., with an additional fixed adjustment for four-wheel drive (4wd) vehicles. This adjustment accounts for the fact that 4wd, critical to enabling many off-road heavy-duty work applications, adds roughly 500 lbs. to the vehicle weight. The work factor is calculated as follows: 75 percent maximum payload + 25 percent of maximum towing + 375 lbs. if 4wd. Under this approach, target GHG and fuel consumption standards are determined for each vehicle with a unique work factor (analogous to a target for each discrete vehicle footprint in the light-duty vehicle rules). These targets will then be production weighted and summed to derive a manufacturer’s annual fleet average standard for its heavy-duty pickups and vans. There was widespread support (and no opposition) for the work factor-based approach to standards and fleet average approach to compliance expressed in

⁴⁶² See 76 FR 57259–57260, September 15, 2011 and 78 FR 36374, June 17, 2013.

⁴⁶³ The NAS 2010 report. See 76 FR 57161.

the comments we received on the Phase 1 rule.

For Phase 2, the agencies proposed to continue using the work-based attribute. The agencies received a variety of comments on the details of the work factor approach. The agencies received comments from The American Council for an Energy-Efficient Economy (ACEEE) regarding the definition of payload and towing and manufacturer's discretion at determining GVWR, GCWR and curb weight of the vehicle. In response, the formula for payload, GVWR minus curb weight, is specified such that it uses the same definition of the input terms as those which have always been used by the agencies for light and heavy duty vehicle regulations, including criteria pollutant emission standards and safety related designations. The agencies feel that there is no ambiguity in the definition of these terms and therefore that payload calculation remains clearly defined with little or no opportunity for manipulation. The agencies have successfully used the previously established definitions of GVWR and curb weight to implement emissions and safety related programs and have not experienced any adverse issues in applying these definitions. The same is true for the definitions of terms used to calculate towing—GCWR minus GVWR. While this definition for towing capacity does not match the method used by manufacturers in their consumer advertising, the agencies determined that the inputs of GCWR and GVWR are clearly defined in our regulations and used for many other emission and safety related determinations and therefore also remain a clear and consistent method to define towing for the purposes of calculating work factor. Again, the agencies have successfully used the previously established definitions of GCWR and have not experienced any issues that would warrant a change to the definition or use of these parameters.

ACEEE commented on recent announcements from two manufacturers that reported increases in payload capacity in their pick-ups due to a decrease in the curb weight of the vehicles from changes to light-weight materials. A reduction in vehicle weight while maintaining the same GVWR will result in a higher payload capacity which will then increase that vehicle's calculated work factor and therefore result in a higher (less stringent) target GHG and fuel consumption standard. Similar to the light-duty (LD) footprint based approach which allows increases in GHG emissions and fuel consumption

with increasing footprints, the work factor is designed to allow increases in GHG emissions and fuel consumption with increases in capability to do work, primarily hauling payload and towing. Decreases in curb weight as described in the comment actually demonstrate that the work factor is operating both appropriately and as the agencies intended. By reducing curb weight, these manufacturers are increasing the work capability of their trucks specifically purchased by consumers to transport payload and (sometimes) to tow. Additional payload capacity, while not always needed, will allow the user to transport more goods resulting in an overall reduction in GHGs and fuel used versus taking additional trips to do the same work. This may differ from light-duty pick-ups where transportation of goods may not be the primary use of the vehicle. Additionally, the reduction in curb weight will be beneficial in all other situations of unloaded and partially loaded transport of goods because a reduction in curb weight of the vehicle results in less energy wasted simply to move the vehicle regardless of payload. For this reason, the agencies included mass reduction as among the technologies on which the stringency of the final standards (as well as the phase 1 standards) is based. Mass reduction is discussed in detail in the technology descriptions section below.

Most of the comments supported the continued use of work factor-based standards for heavy duty pickups and vans. The agencies received several comments regarding surplus towing. The American Automotive Policy Council (AAPC) commented that existing NHTSA Federal Motor Vehicle Safety Standards effectively cap the towing and GCWR in this vehicle segment. Cummins noted that the curves were data-based in Phase 1 and any changes to the curves would require a full study, similar to Phase 1, in order to ensure feasibility and a fair framework for all OEMs. Daimler commented in support of changing weighting of payload to 80 percent and towing to 20 percent of work factor formula and did not oppose a cap on towing. Several commenters supported adopting a mechanism to minimize the incentive the standards provide to increase work factor. ACEEE supported further considering changing the shape of the standards curves, shown below in Figure VI-3 and Figure VI-4, to be flatter at higher work factors. Honeywell commented that towing capacity has increased significantly over the last five years, beyond the needs of most buyers, and that the curves should be flattened

starting at 7,500 lbs, noting that this change would impact less than 10 percent of all class 2b/3 vehicles. The International Council on Clean Transportation (ICCT) similarly suggested a cut point of 5,500 lbs. for gasoline trucks and 8,000 lbs. for diesels, based on these cutpoints being near the 90th percentile for the model year 2014 fleet. The Union of Concerned Scientists (UCS) (like ACEEE) commented that light-weighting is being used to increase payload and also supported leveling off the curves to eliminate the incentive to add payload and towing capacity.

After considering these comments, the agencies concluded that the work factor approach established in the Phase 1 rule appropriately accounts for the different utility aspects of heavy-duty vehicles. While trucks and vans may be used differently depending on the required job, the three main attributes of payload, towing and four wheel drive remain properly accounted for at this time in the work factor equation at the current weightings. While a small portion of the fleet may be considered to have excess towing capacity relative to the actual required towing capacity by the customer, the agencies determined that the work factor design does not necessarily result in an incentive for manufacturers to build excessive towing into the vehicle design. Towing capacity increases require improvements to vehicle powertrains, cooling and brakes, generally at the expense of payload, and therefore the work factor reasonably balances an increase in towing with a reduction in payload. Additionally, increases in vehicle weight for additional towing capacity may result in an increase in the emission test weight, further penalizing unnecessary towing capacity. Moreover, as AAPC discusses in their comments, towing and payload are effectively already capped by existing NHTSA safety requirements in this segment. Consumers will ultimately decide on the appropriate balance of payload and towing for their applications, and the agencies therefore believe that establishing a work factor cap for the small percentage of vehicles with the highest towing capabilities is not necessary and will not result in emission increases or fuel consumption reductions under the high towing conditions for which those vehicles were purchased.

The agencies also received comments regarding making changes to the work factor formula for vans. AAPC commented that the payload, towing, and 4wd inputs do not fully represent the intended uses of cargo and passenger vans, where cargo or

passenger volumes are of primary importance. AAPC recommended that the agencies add a volumetric term to the work factor for vans with high (208 cubic feet or greater) cargo and passenger volumes. Vans with high volumes would have higher work factors and therefore less stringent targets with the AAPC recommended formula compared to the current formula. ACEEE commented that the work factor is a far better predictor of fuel efficiency for pickups than for vans and offered general support for adopting different work factor formulas for pickups and vans.

While it is likely that a portion of the vans are used exclusively for cargo volume and that towing is not an important attribute for these vans, the commenter failed to provide sufficient new information to support a new work factor metric specifically to address cargo focused vans. The commenter's suggested modification does not sufficiently represent the different van cargo volumes available to consumers today. A cargo volume based modification requires a complete industry van analysis of all available van cargo volumes and GHG and fuel economy performance levels from which an appropriately normalized adjustment would be determined, consistent with the approach used to establish the existing work factor equation for the attributes of payload, towing and four wheel drive. The agencies did not receive the level of detailed information required to determine the impact of cargo volume and establish a work factor correlation. Accordingly, the agencies are not incorporating the suggested change to the work factor for vans.

As noted in the Phase 1 rule, the attribute-based CO₂ and fuel consumption standards are meant to be as consistent as practicable from a stringency perspective. Vehicles across the entire range of the HD pickup and van segment have their respective target values for CO₂ emissions and fuel consumption, and therefore all HD pickups and vans will be affected by the standard. With this attribute-based standards approach, EPA and NHTSA continue to believe there should be no significant effect on the relative distribution of vehicles with differing capabilities in the fleet, which means that buyers should still be able to purchase the vehicle that meets their needs.

(b) Standards

The agencies are adopting Phase 2 standards as proposed based on analyses performed to determine the

appropriate HD pickup and van Phase 2 standards and the most appropriate phase in of those standards. These analyses, described below and in the Final RIA, considered:

- projections of future U.S. sales for HD pickups and vans
- the estimates of corresponding CO₂ emissions and fuel consumption for these vehicles
- forecasts of manufacturers' product redesign schedules
- the technology available in new MY 2014 HD pickups and vans to specify preexisting technology content to be included in the analysis fleet (the fleet of vehicles used as a starting point for analysis) extending through MY 2030
- the estimated effectiveness, cost, applicability, and availability of technologies for HD pickup and vans
- manufacturers' ability to use credit carry-forward
- the levels of technology that are projected to be added to the analysis fleet through MY 2030⁴⁶⁴ considering improvements needed in order to achieve compliance with the Phase 1 standards (thus defining the reference fleet—*i.e.*, under the No-Action Alternative—relative to which to measure incremental impacts of Phase 2 standards), and
- the levels of technology that are projected to be added to the analysis fleet through MY 2030 considering further improvements needed in order to achieve compliance with standards defining each regulatory (action) alternative for Phase 2.

Based on this analysis, EPA is adopting as proposed CO₂ attribute-based target standards shown in Figure VI-3 and Figure VI-4, and NHTSA is adopting as proposed the equivalent attribute-based fuel consumption target standards, also shown in Figure VI-3 and Figure VI-4, applicable in model year 2021–2027. As shown in these figures, the Phase 2 standards will be phased in year-by-year commencing in MY 2021. The agencies did not propose and are not adopting changes to the standards for 2018–2020 and therefore the standards will remain at the MY 2018 Phase 1 levels for MYs 2019 and 2020. EISA requires four years of lead-time and three years stability for NHTSA standards and this period of lead-time and stability for 2018–2020 is thus consistent with the EISA requirements. For MYs 2021–2027, the agencies are finalizing as proposed annual reductions (*i.e.*, increases in

stringency) in the standards. These standards become 16 percent more stringent overall between MY 2020 and MY 2027, compared to the MY 2018 Phase 1 levels. This approach to the Phase 2 standards as a whole can be considered a phase-in or implementation schedule of the MY 2027 standards (which, as noted, will apply thereafter unless and until amended).

For EPA, Section 202(a) (1) provides the Administrator with the authority to establish standards, and to revise those standards “from time to time,” thus providing the Administrator with considerable discretion in deciding when to revise the Phase 1 MY 2018 standards. As noted above, EISA requires that NHTSA provide four full model years of regulatory lead time and three full model years of regulatory stability for its fuel economy standards. See 49 U.S.C. 32902(k)(3).

Congress has not spoken directly to the meaning of the words “regulatory stability.” NHTSA believes that the “regulatory stability” requirement exists to ensure that manufacturers will not be subject to new standards in repeated rulemakings too rapidly, given that Congress did not include a minimum duration period for the MD/HD standards.⁴⁶⁵ NHTSA further believes that standards, which as set provide for increasing stringency during the period that the standards are applicable under this rule to be the maximum feasible during the regulatory period, are within the meaning of the statute. In this statutory context, NHTSA interprets the phrase “regulatory stability” in Section 32902(k)(3)(B) as requiring that the standards remain in effect for three years before they may be increased by amendment. It does not prohibit standards which contain predetermined stringency increases.”

Consistent with these authorities, the agencies are adopting more stringent standards beginning with MY 2021, and ending with MY 2027, that consider the level of technology we judge can be applied to new vehicles at reasonable cost to meet the standards. EPA believes the Phase 2 standards are consistent with CAA requirements regarding lead-time, cost, feasibility, and safety. NHTSA believes the Phase 2 standards are the maximum feasible under EISA. Manufacturers in the HD pickup and van market segment have relatively few vehicle lines and redesign cycles are typically longer compared to light-duty vehicles. Also, the timing of vehicle

⁴⁶⁴ Although the final standards are implemented in MY 2027, the model looks out to MY 2030 to help account for the potential use of credit carry-forward provisions.

⁴⁶⁵ In contrast, light-duty standards must remain in place for “at least 1, but not more than 5, model years.” 49 U.S.C. 32902(b)(3)(B).

redesigns differs among manufacturers. To provide lead time needed to accommodate these longer redesign cycles, the Phase 2 GHG standards will not reach their highest stringency until 2027. Although these standards will become more stringent each year between MYs 2021 and 2027, the agencies expect manufacturers will likely make improvements as part of planned redesigns, such that some model years will likely involve significant advances, while other model years will likely involve little change. The agencies also expect manufacturers to use program flexibilities (*e.g.*, credit carry-forward provisions and averaging and banking provisions) to help achieve compliance without compressing redesign schedules and to efficiently manage resources and capital over time. The MY 2018 standards are unchanged in MYs 2019–2020 to provide necessary lead time for the Phase 2 standards. However, some manufacturers may choose to begin implementing technologies earlier (in some cases potentially as soon as MY 2017) depending on their vehicle redesign cycles. Although standards are not changing in MYs 2019–2020, manufacturers may introduce additional technologies in order to earn credits that may be carried-forward under the 5 year credit carry-forward provisions established in Phase 1 and continuing for Phase 2.

The agencies received several comments on the Phase 2 standards and the technological basis and feasibility of the standards. The comments are discussed in Sections VI.D and 0below, which provide additional discussion of vehicle redesign cycles and the feasibility of the final Phase 2 standards, and also in Section 7 of the Response to Comments document.

Recognizing that it is unlikely that there is a phase-in approach that equally fits with all manufacturers' unique product redesign schedules, the agencies requested comments on other ways the Phase 2 standards could be phased in. The agencies suggested one alternative approach would be to phase in the standards in a few step changes, for example in MYs 2021, 2024 and 2027 (as with the standards for vocational vehicles, tractors, trailers, and the heavy duty engine standards). Under this example, if the step changes on the order of 5 percent, 10 percent,

and 16 percent improvements from the MY 2020 baseline in MYs 2021, 2024 and 2027 respectively, the program would provide CO₂ reductions and fuel improvements roughly equivalent to the approach being adopted. EPA did not receive comments on this alternative phase-in approach, which closely resembles the phase-in approach used for the other sectors.

AAPC commented in support of an alternative year-over-year phase-in that would phase-in stringency more gradually than proposed (and now adopted). AAPC recommended that rather than a 2.5 percent per year improvement, the increase should be at 1.75 percent per year through MY 2024 and then 3.5 percent per year for MY 2025 through 2027 with the MY 2027 level of stringency equally the proposed level. AAPC commented that this more gradual approach was consistent with the Phase 1 phase-in approach and would help manufacturers manage the long lead time associated with developing the new vehicles and powertrains that will be required in order to comply with the Phase 2 proposal.

The agencies are finalizing the proposed phase-in rather than adopting the approach recommended by AAPC. The more gradual phase-in recommended by AAPC would result in a loss of program benefits in each of the interim years of the program compared to the promulgated standards until the phase-in caught up with that phase-in in MY 2027. Because of the slower phase-in, the overall reduction in each interim year is lower than the phase-in being finalized. The phase-in adopted for Phase 1 with a more gradual ramp-up in standards took into consideration the shorter lead time associated with the Phase 1 standards and the uncertainty associated with implementing a new program. Phase 2 provides more lead-time than Phase 1 and the agencies believe based on their analyses of the standards that the lead-time provided is sufficient, particularly considering the flexibility also provided by credit carry-forward and carry-back provisions.

As with Phase 1 (and like the light-duty vehicle standards), the Phase 2 standards must be met on a production-weighted fleet average basis. No individual vehicle will have to meet a particular target (or the individual fleet average level). Each manufacturer will

also have its own fleet average standard. Specifically, each manufacturer will have its own unique fleet average requirement based on the production-weighted average of the heavy duty pickups and vans it chooses to produce. Moreover, averaging, banking, and trading provisions, just alluded to and discussed further below, will provide significant additional compliance flexibility in implementing the standards. It is important to note, however, that while the standards will differ numerically from manufacturer to manufacturer, effective stringency should be essentially the same for each manufacturer. The agencies did not receive comments suggesting changes to this general averaging approach to establishing the standards.

Also, as with the Phase 1 standards, the agencies proposed and are finalizing separate Phase 2 targets for gasoline-fueled (and any other Otto-cycle) vehicles and diesel-fueled (and any other diesel-cycle) vehicles. See 80 FR 40337. The targets will be used to determine the production-weighted fleet average standards that apply to the combined diesel and gasoline fleet of HD pickups and vans produced by a manufacturer in each model year. The stringency increase discussed above for Phase 2 applies equally to the separate gasoline and diesel targets. For the proposal, the agencies considered different rates of increase for the gasoline and diesel targets in order to more equally balance compliance burdens across manufacturers with varying gasoline/diesel fleet mixes. However, at least among major HD pickup and van manufacturers, our analyses suggested limited potential for such optimization, especially considering uncertainties involved with manufacturers' future fleet mix. The agencies did not receive comments on the specific topic of maintaining equivalent rates of increase for gasoline and diesel-fueled vehicles. The agencies, however, received several comments regarding maintaining separate standards for the two vehicle types. Some of the comments recommended closing the gap between diesel and gasoline-fueled vehicles by making the gasoline-fueled vehicle standards more stringent. These comments are discussed below.

Figure VI-3 EPA Phase 2 CO₂ Target Standards and NHTSA Fuel Consumption Target Standards for Diesel HD Pickups and Vans

Figure VI-4 EPA Phase 2 CO₂ Target Standards and NHTSA Fuel Consumption Target Standards for Gasoline HD Pickups and Vans

Described mathematically, EPA's and NHTSA's target standards are defined by the following formulas:

$$\text{EPA CO}_2 \text{ Target (g/mile)} = [a \times \text{WF}] + b$$

NHTSA Fuel Consumption Target (gallons/100 miles) = $[c \times \text{WF}] + d$

Where:

WF = Work Factor = $[0.75 \times (\text{Payload Capacity} + \text{xwd})] + [0.25 \times \text{Towing Capacity}]$

Payload Capacity = GVWR (lb.) – Curb Weight (lb.)

xwd = 500 lbs. if the vehicle is equipped with 4wd, otherwise equals 0 lbs.

Towing Capacity = GCWR (lb.) – GVWR (lb.)
Coefficients a, b, c, and d are taken from Table VI-2.

Note:

^a Phase 1 primary phase-in coefficients. Alternative phase-in coefficients are different in MY 2018 only.

As noted above, the agencies did not propose and are not adopting changes from the final Phase 1 standards for MYs 2018–2020. The MYs 2018–2020 standards are shown in the figures and tables above for reference. The agencies did not receive comments recommending changes to the standards in these model years.

NHTSA and EPA have also analyzed regulatory alternatives to these standards, as discussed in Sections VI.D and 0 and Section X. below. The agencies requested comment on all of the alternatives analyzed for the proposal, but requested comment on Alternative 4 in particular. The agencies did not propose Alternative 4 because EPA and NHTSA had outstanding questions regarding relative risks and benefits of Alternative 4 due to the timeframe envisioned by that alternative. As noted above, Alternative 4 would have provided less lead time for the complete phase-in of the Phase 2 standards based on an annual improvement of 3.5 percent per year in MYs 2021–2025 compared to the Alternative 3 per year improvement of 2.5 percent in MYs 2021–2027.

In the proposal, the agencies requested comments, data, and information that would help inform determination of the maximum feasible (for NHTSA) and appropriate (for EPA) stringency for HD pickups and vans and are particularly interested in information and data related to the expected adoption rates of different emerging technologies, such as mild and strong hybridization. The agencies received comments both in support of

and not in support of Alternative 4 and also received comments in support of standards more stringent than either the proposal or the Alternative 4 pull ahead. The comments regarding stringency and feasibility are discussed in Sections VI.D and E. As described in these sections, and in Section X and RIA Chapter 11, NHTSA and EPA believe the final Phase 2 standards represent, respectively, the maximum feasible standards under EISA and the most stringent standards reasonably achievable under the CAA considering lead-time, reasonable cost, feasibility, and safety.

As with Phase 1 standards, to calculate a manufacturer's HD pickup and van fleet average standard, the agencies proposed and are finalizing separate target curves for gasoline and diesel vehicles in Phase 2. While diesel and gasoline vehicles have separate work factor-based target standard curves, all of a manufacturer's vehicles are averaged together as a single averaging set to demonstrate compliance. As noted above, the agencies' Phase 2 standards are estimated to result in approximately 16 percent reductions in CO₂ and fuel consumption for both diesel and gasoline vehicles relative to the MY 2018 Phase 1 standards for HD pickup trucks and vans.

The agencies requested comment on both the level of stringency of the standards and the continued separate targets for gasoline and diesel HD pickups and vans. AAPC supported the agencies' proposal to maintain separate targets noting that the approach ensures

that manufacturers of either engine type will implement the latest CO₂ reducing technologies. AAPC further commented that significant technological and market-based differences exist between heavy-duty gasoline and heavy-duty diesel engines. According to the commenter, maintaining separate but comparably stringent spark ignition and compression ignition targets will allow customers for specific applications to take advantage of the combustion technology that best meets their specific application requirements.

Several commenters did not support the proposed approach but instead supported setting a single fuel-neutral set of targets. Cummins commented that there is sufficient lead-time and technology to create a pathway to fuel-neutral targets, and that fuel neutral targets would eliminate any competitive advantage or preference to a particular GHG/FE technology and maintain the environmental benefits envisioned for the program. Daimler, Honeywell, and MEMA similarly commented in support of fuel-neutral standards. Honeywell and Motor and Equipment Manufacturers Association (MEMA) suggested basing the standards on a 16 percent improvement from the projected MY 2018 gasoline/diesel combined baseline. ACEEE and ICCT commented in support of a single set of standards set at or close to the capabilities of diesel technology. These commenters suggested that gasoline engines should be subject to more stringent standards than proposed and that gasoline and diesel engines should be held to the same performance-based standards.

Bosch disagreed with maintaining separate targets for gasoline and diesel HD pickups and vans. Bosch recommended that targets be fuel neutral, as they are in the light-duty vehicle programs. Bosch commented that it “believes that a market shift towards spark-ignited vehicles and away from HD pickups and vans powered by “fundamentally more efficient” CI engines would be a very real possibility under Phase 2 if the separate gasoline and diesel targets are finalized as proposed.” Bosch continues that “any such shift would signify not only a move towards less efficient internal combustion engines, but would be counterproductive from a programmatic/environmental and energy standpoint.” Bosch further commented that “diesels from a criteria pollutant (especially NO_x emissions perspective, have made far greater strides over the years than gasoline engines, and for that reason have incurred greater technological development costs than the latter. While equivalent CO₂ target values may be more expensive, comparatively speaking, for SI engines to achieve (based on the agencies’ cost analysis), the additional cost imposed on these engines likely would not rise to the level of, much less overtake CI engines’ historically higher technological development and system costs.”

The agencies generally prefer to set standards that do not distinguish between fuel types where technological or market-based reasons do not strongly argue otherwise. However, as with Phase 1, we continue to believe that fundamental differences between spark ignition and compression ignition engines warrant unique fuel standards, which is also important in ensuring that our program maintains product choices available to vehicle buyers. In fact, gasoline and diesel fuel behave so differently in the internal combustion engine that they have historically required unique test procedures, emission control technologies and emission standards. These technological differences between gasoline and diesel engines for GHGs and fuel consumption exist presently and will continue to exist after Phase 1 and through Phase 2 until advanced research evolves the gasoline fueled engine to diesel-like efficiencies. This will require significant technological breakthroughs currently in early stages of research such as homogeneous charge compression ignition (HCCI) or similar concepts. Because these technologies are still in the early research stages, we believe the separate fuel type standards are

appropriate in the timeframe of this rule to assure the availability of both gasoline and diesel engines. We also project that these separate standards will result in roughly equivalent redesign burdens for engines of both fuel types as evidenced by feasibility and cost analysis in RIA Chapter 10. For the same reasons, the agencies are adopting separate standards for diesel and SI vocational engines. See Section V. above.

In order to maintain the same overall level of stringency as proposed for the program, a fuel neutral standard would result in an increase in stringency for gasoline or spark ignition vehicles with a matching relaxation of stringency for diesel or compression ignition vehicles relative to the separate numerical levels established in the proposal for gasoline and diesel vehicles. Based on the analysis of available technologies for both types of vehicles, the agencies do not feel it is appropriate to adopt such a change for either gasoline or diesel vehicles. This change could lead to an undesirable reduction in penetration of fuel efficient technologies in diesels, particularly from manufacturers who produce predominately diesel vehicles, while requiring a higher penetration of advanced technologies like strong hybridization in gasoline vehicles, distorting consumer choice. Additionally, the agencies do not agree with the comment stating that maintaining separate gasoline and diesel targets of equal increases in stringency of 2.5 percent per year from the Phase 1 final standards will result in a shift to less efficient gasoline vehicles. The agencies determined that manufacturers have similar technology challenges and corresponding costs regardless of fuel type and therefore manufacturers do not have an easier or lower cost long term path to compliance by simply shifting production from one fuel type to the other.

Note further that a manufacturer’s fleet average standard is the production weighted average of *all* its targets, both gasoline and diesel. Thus, there is no separate gasoline vehicle standard, or separate diesel standard. Commenters may have been confused on this point (several of the commenters referred to gasoline ‘standards’, or diesel ‘standards’). This averaging feature of the standard further increases incentives to add advanced technologies to either gasoline or diesel vehicles if manufacturers perceive it advantageous to do so, since the benefit is experienced fleet wide, not just for the gasoline or diesel segment of a manufacturer’s production line.

The NHTSA fuel consumption target curves and EPA GHG target curves are equivalent. The agencies established the target curves using the direct relationship between fuel consumption and CO₂ using conversion factors of 8,887 g CO₂/gallon for gasoline and 10,180 g CO₂/gallon for diesel fuel.

It is expected that measured performance values for CO₂ will generally be equivalent to fuel consumption. However, Phase 1 established a provision that EPA is not changing for Phase 2 that allows manufacturers, if they choose, to use CO₂ credits to help demonstrate compliance with N₂O and CH₄ emissions standards, by expressing any N₂O and CH₄ under compliance in terms of their CO₂-equivalent and applying CO₂ credits as needed. For test families that do not use this compliance alternative, the measured performance values for CO₂ and fuel consumption will be equivalent because the same test runs and measurement data will be used to determine both values, and calculated fuel consumption will be based on the same conversion factors that are used to establish the relationship between the CO₂ and fuel consumption target curves (8,887 g CO₂/gallon for gasoline and 10,180 g CO₂/gallon for diesel fuel). For manufacturers that choose to use EPA provision for CO₂ credit use in demonstrating N₂O and CH₄ compliance, compliance with the CO₂ standard will not be directly equivalent to compliance with the NHTSA fuel consumption standard.

(2) What are the HD pickup and van test cycles and procedures?

The Phase 1 program established testing procedures for HD pickups and vans and NHTSA and EPA are maintaining these testing protocols. The vehicles will continue to be tested using the same heavy-duty chassis test procedures currently used by EPA for measuring criteria pollutant emissions from these vehicles, including the city fuel economy test cycle (FTP) and the highway fuel economy test cycle (HFET). These test procedures are used by manufacturers for certification and emissions compliance demonstrations and by the agencies for compliance verification and enforcement. While the FTP and the HFET driving patterns are identical to that of the light-duty test cycles, other test parameters for running them, such as test vehicle loaded weight, are specific to complete heavy-duty vehicles. Please see Section II.C (2) of the Phase 1 Preamble (76 FR 57166) for a discussion of how HD pickups and vans are tested.

The test procedures for HD pickups and vans currently specify using a fuel with properties established under the light-duty (LD) vehicle Tier 2 program. EPA recently finalized new emission standards under the Tier 3 program for both LD vehicles and HD pickups and vans which will begin to phase-in in MY 2017 for LD vehicles and MY 2018 for vehicles over 6000 pounds GVWR, including HD pickups and vans. As part of the Tier 3 program, new test procedures for gasoline-fueled vehicles requiring the use of a new test fuel containing 10 percent ethanol which is more representative of in-use fuel that the vehicles will encounter. The agencies are investigating any potential impact of changes to the fuel properties on GHG emissions and fuel consumption and have committed to providing appropriate adjustment to the test procedures if necessary to ensure no change in stringency of the Phase 1 or the Phase 2 standards.

AAPC commented that the current methodology of grouping vehicles by the Equivalent Test Weight (ETW) in increments of 500 pounds for determining their GHG and FE performance is too large to capture weight reductions that may occur within a 500 pound grouping. Under the current test procedures, vehicles are tested at 500 lb. increments of inertial weight classes when testing at or above 5500 lbs. test weight. For example, the commenter stated that all vehicles having a calculated test weight basis of 11,251 to 11,750 lbs. are tested at 11,500 lbs. (*i.e.*, the midpoint of the range). However, for some vehicles, the existence of these bins and the large intervals between bins may reduce or eliminate the incentive for mass reduction for some vehicles, as a vehicle may require significant mass reduction before it could switch from one test weight bin to the next lower bin. For other vehicles, these bins may unduly reward relatively small reductions of vehicle mass, as a vehicle's mass may be only slightly greater than that needed to be assigned a 500-pound lighter inertia weight class. For example, for a vehicle with a calculated test weight basis of 11,700 lbs., a manufacturer would receive no regulatory benefit for reducing the vehicle weight by 400 lbs., because the vehicle would stay within the same weight bracket.

The agencies believe this (and similar comments) have some merit. In response, the agencies are finalizing an option allowing manufacturers to divide vehicle models into finer weight groupings of vehicles for the different Adjusted Loaded Vehicle Weights (ALVW) for purposes of more precise

calculation of CO₂ emissions performance within the 500 pound increment test weight classes. Manufacturers will be able to select 50, 100, 250, or 500 weight groups for reporting emissions. ALVW will vary within a single ETW largely depending on the varying models curb weights from customer option selection and other production variations. The calculation of CO₂ emissions performance for the finer groupings is performed as described in 40 CFR 86.1819–14(g)) for analytically adjusting CO₂ (ADCO₂) emissions. The test results at the existing 500 pound increment ETWs will be used to determine the CO₂ emissions performance level of the new groupings using the analytically derived equation. This new ADCO₂ emissions level is only used for this new grouping and cannot be used to extend determination of other ALVW groupings emission performance levels. The vehicle specific values used to determine the change in ETW in the ADCO₂ emissions calculation to estimate the performance of the smaller grouping should be consistent with value used to calculate the single work factor of that same grouping. This change does not impact the ETW of a group of vehicle models that are contained in the 500 pound increment of ETW when performing testing nor does it eliminate any vehicle in that grouping from being responsible for emission performance at the 500 pound increment test weight classes. As described, this change only allows for more precise CO₂ emissions estimation for the potentially different curb weights of vehicles grouped in a single ETW class for purposes of fleet average calculation. If a manufacturer chooses to use less than 500 pound increments, they are required to use this option for all of their HD vehicles that are chassis certified (including loose engines).

(3) Fleet Average Standards

As proposed, and as noted above, NHTSA and EPA are retaining the fleet average standards approach finalized in the Phase 1 rule and structurally similar to light-duty Corporate Average Fuel Economy (CAFE) and GHG standards. The fleet average standard for a manufacturer is a production-weighted average of the work factor-based targets assigned to unique vehicle configurations within each model type produced by the manufacturer in a model year, with separate targets for gasoline and diesel vehicles (which are then combined into a production weighted average which comprises that manufacturer's fleet average standard). Each manufacturer will continue to

have an average GHG requirement and an average fuel consumption requirement unique to its new HD pickup and van fleet in each model year, depending on the characteristics (payload, towing, and drive type, as well as gasoline and diesel) of the vehicle models produced by that manufacturer, and on the U.S.-directed production volume of each of those models in that model year. Vehicle models with larger payload/towing capacities and/or four-wheel drive have individual targets at numerically higher CO₂ and fuel consumption levels than less capable vehicles, as discussed in Section VI.B.(1). The agencies did not receive comments suggesting changes to this fundamental approach to the standards.

The fleet average standard with which the manufacturer must comply will continue to be based on its final production figures for the model year, and thus a final assessment of compliance will occur after production for the model year ends. The assessment of compliance also must consider the manufacturer's use of carry-forward and carry-back credit provisions included in the averaging, banking, and trading program. Because compliance with the fleet average standards depends on actual test group production volumes, it is not possible to determine compliance at the time the manufacturer applies for and receives an (initial) EPA certificate of conformity for a test group. Instead, at certification the manufacturer will demonstrate a level of performance for vehicles in the test group, and make a good faith demonstration that its fleet, regrouped by unique vehicle configurations within each model type, is expected to comply with its fleet average standard when the model year is over. EPA will issue a certificate for the vehicles covered by the test group based on this demonstration, and will include a condition in the certificate that if the manufacturer does not comply with the fleet average, then production vehicles from that test group will be treated as not covered by the certificate to the extent needed to bring the manufacturer's fleet average into compliance. As in the parallel program for light-duty vehicles, additional "model type" testing will be conducted by the manufacturer over the course of the model year to supplement the initial test group data. The emissions and fuel consumption levels of the test vehicles will be used to calculate the production-weighted fleet averages for the manufacturer, after application of the appropriate deterioration factor to each result to obtain a full useful life value.

Please see Section II.C.(3)(a) of the Phase 1 Preamble (76 FR 57167) for further discussion of the fleet average approach for HD pickups and vans.

(4) In-Use Standards

Section 202(a)(1) of the CAA specifies that EPA set emissions standards that are applicable for the useful life of the vehicle. EPA will continue the in-use standards approach for individual vehicles that EPA finalized for the Phase 1 program. NHTSA did not adopt Phase 1 in-use standards and did not propose in-use standards for Phase 2. For the EPA program, compliance with the in-use standard for individual vehicles and vehicle models does not impact compliance with the fleet average standard, which will be based on the production-weighted average of the new vehicles. Vehicles that fail to meet their in-use emission standards will be subject to recall to correct the noncompliance. NHTSA is finalizing the use of EPA's useful life requirements to ensure manufacturers consider in the design process the need for fuel efficiency standards to apply for the same duration and mileage as EPA standards. NHTSA will limit such penalties to situations in which it determined that the vehicle or engine manufacturer failed to comply with the standards.

As with Phase 1, the in-use Phase 2 GHG standards for HD pickups and vans will be established by adding an adjustment factor to the full useful life emissions used to calculate the GHG fleet average. Each model's in-use CO₂ standard will be the model-specific level used in calculating the fleet average, plus 10 percent. No adverse comments were received on this provision. Please see Section II.C.(3)(b) of the Phase 1 Preamble (76 FR 57167) for further discussion of in-use standards for HD pickups and vans. This provision, along with the continuation of the Phase 1 test procedures, eliminates that need for the agencies to include any additional compliance margin in our feasibility analysis.

For Phase 1, EPA aligned the useful life for GHG emissions with the useful life that was in place for criteria pollutants: 11 years or 120,000 miles, whichever occurs first (40 CFR 86.1805–04(a)). Since the Phase 1 rule was finalized, EPA updated the useful life for criteria pollutants as part of the Tier 3 rulemaking.⁴⁶⁶ The new useful life implemented for Tier 3 is 150,000 miles or 15 years, whichever occurs first. As

proposed, the useful life for GHG emissions and fuel consumption will also be 150,000 miles/15 years starting in MY 2021 when the Phase 2 standards begin so that the useful life remains aligned for GHG and criteria pollutant standards long term. The agencies did not receive adverse comments on this provision.

(5) Other GHG Standards for HD Pickups and Vans

This section addresses greenhouse gases other than CO₂. Note that since these are greenhouse gases not directly related to fuel consumption, NHTSA does not have equivalent standards.

(a) Nitrous Oxide (N₂O) and Methane (CH₄)

In the Phase 1 rule, EPA established emission standards for HD pickups and vans for both nitrous oxide (N₂O) and methane (CH₄). Similar to the CO₂ standard approach, the N₂O and CH₄ emission levels of a vehicle are based on a composite of the light-duty FTP and HFET cycles with the same 55 percent city weighting and 45 percent highway weighting. The N₂O and CH₄ standards were both set by EPA at 0.05 g/mile. Unlike the CO₂ standards, averaging between vehicles is not allowed. The standards are designed to prevent increases in N₂O and CH₄ emissions from current levels, *i.e.*, a no-backsliding standard. EPA did not propose and is not adopting any changes the N₂O or CH₄ standards or related provisions established in the Phase 1 rule. Please see Phase 1 Preamble Section II.E. (76 FR 57188–57193) for additional discussion of N₂O and CH₄ emissions and standards.

Across both current gasoline- and diesel-fueled heavy-duty vehicle designs, emissions of CH₄ and N₂O are relatively low and the intent of the cap standards is to ensure that future vehicle technologies or fuels do not result in an increase in these emissions. Given the global warming potential (GWP) of CH₄, the 0.05 g/mile cap standard is equivalent to about 1.7 g/mile CO₂, which is much less than 1 percent of the overall GHG emissions of most HD pickups and vans.⁴⁶⁷ The effectiveness of oxidation of CH₄ using a three-way or diesel oxidation catalyst is limited by the activation energy, which tends to be higher where the number of carbon atoms in the hydrocarbon molecule is low and thus CH₄ is very stable. At this time we are not aware of any technologies beyond the already present catalyst systems

which are highly effective at oxidizing most hydrocarbon species for gasoline and diesel fueled engines that would further lower the activation energy across the catalyst or increase the energy content of the exhaust (without further increasing fuel consumption and CO₂ emissions) to further reduce CH₄ emissions at the tailpipe. The CH₄ standard remains an important backstop to prevent future increases in CH₄ emissions. EPA did not receive adverse comments regarding the proposal to not change the CH₄ standard for HD pickups and vans.

N₂O is emitted from gasoline and diesel vehicles mainly during specific catalyst temperature conditions conducive to N₂O formation. The 0.05 g/mile standard, which translates to a CO₂-equivalent value of 14.9 g/mile, ensures that systems are not designed in a way that emphasizes efficient NO_x control while allowing the formation of significant quantities of N₂O. The Phase 1 N₂O standard of 0.05 g/mile for pickups and vans was finalized knowing that it is more stringent than the Phase 1 N₂O engine standard of 0.10 g/hp-hr, which is being continued for Phase 2, as discussed in Section II.D.3. EPA continues to believe that the 0.05 g/mile standard provides the necessary assurance that N₂O will not significantly increase, given the mix of gasoline and diesel fueled engines in this market and the upcoming implementation of the light-duty and heavy-duty (up to 14,000 lbs. GVWR) Tier 3 NO_x standards. EPA knows of no technologies that would lower N₂O emissions beyond the control provided by the precise emissions control systems already being implemented to meet EPA's criteria pollutant standards. Therefore, EPA continues to believe the 0.05 g/mile N₂O standard remains appropriate.

The California Air Resources Board (CARB) suggested that EPA investigate the feasibility of more stringent tailpipe standards. EPA may consider more stringent standards in the future if data is available to support adjustments to the standards as appropriate and consistent with the CAA, but we repeat that at present we know of no further emission reduction technologies for either N₂O or CH₄.

If a manufacturer is unable to meet the N₂O or CH₄ cap standards, the EPA program allows the manufacturer to comply using CO₂ credits. In other words, a manufacturer may offset any N₂O or CH₄ emissions above the standard by taking steps to further reduce CO₂. A manufacturer choosing this option would use GWPs to convert its measured N₂O and CH₄ test results that are in excess of the applicable

⁴⁶⁶ 79 FR 23492, April 28, 2014 and 40 CFR 86.1805–17.

⁴⁶⁷ N₂O has a GWP of 298 and CH₄ has a GWP of 34 according to the IPCC AR5.

standards into CO₂eq to determine the amount of CO₂ credits required. For example, for Phase 1, a manufacturer would use 25 Mg of positive CO₂ credits to offset 1 Mg of negative CH₄ credits or use 298 Mg of positive CO₂ credits to offset 1 Mg of negative N₂O credits.⁴⁶⁸ By using the GWP of N₂O and CH₄, the approach recognizes the inter-correlation of these compounds in impacting global warming and is environmentally neutral for demonstrating compliance with the individual emissions caps. Because fuel conversion manufacturers certifying under 40 CFR part 85, subpart F, do not participate in ABT programs, EPA included in the Phase 1 rule a compliance option for fuel conversion manufacturers to comply with the N₂O and CH₄ standards that is similar to the credit program described above. See 76 FR 57192. The compliance option will allow conversion manufacturers, on an individual engine family basis, to convert CO₂ over compliance into CO₂ equivalents (CO₂ eq) of N₂O and/or CH₄ that can be subtracted from the CH₄ and N₂O measured values to demonstrate compliance with CH₄ and/or N₂O standards. EPA did not include similar provisions allowing over compliance with the N₂O or CH₄ standards to serve as a means to generate CO₂ credits because the CH₄ and N₂O standards are cap standards representing levels that all but the worst vehicles should already be well below. Allowing credit generation against such cap standard would provide a windfall credit without any true GHG reduction. As proposed, EPA is maintaining these provisions for Phase 2 as they provide important flexibility without reducing the overall GHG benefits of the program.

EPA requested comments on updating GWPs used in the calculation of credits discussed above. For Phase 2, EPA is updating the GWP for methane from 25 to 34 based on IPCC AR5. Please see the full discussion of this issue provided in Sections II.D and XI.D.

CARB suggested that EPA consider eliminating or at least phasing out the use of CO₂ credits in lieu of compliance with tailpipe methane standards. In contrast, NGV America strongly supported extending this compliance option, noting that the ability to offset methane (and also nitrous oxide) emissions with CO₂ credits is critical for new natural gas engines and vehicles. Cummins also commented in support of continuing to allow the use of CO₂-equivalent credits to comply with N₂O

and CH₄ standards. Cummins commented that the flexibility has been applied by various manufacturers in Phase 1 and is necessary for Phase 2. Review of MY 2014 certification GHG data confirmed that several manufacturers utilized this Phase 1 program flexibility for either N₂O or CH₄ debits on their diesel vehicles. EPA continues to believe this flexibility is appropriate as it provides important flexibility to manufacturers in an environmentally neutral manner.

(b) Air Conditioning Related Emissions

Air conditioning systems contribute to GHG emissions in two ways—direct emissions through refrigerant leakage and indirect exhaust emissions due to the extra load on the vehicle's engine to provide power to the air conditioning system. HFC refrigerants, which are powerful GHG pollutants, can leak from the A/C system. This includes the direct leakage of refrigerant as well as the subsequent leakage associated with maintenance and servicing, and with disposal at the end of the vehicle's life.⁴⁶⁹ Currently, the most commonly used refrigerant in automotive applications—R134a, has a high GWP. Due to the high GWP of R134a, a small leakage of the refrigerant has a much greater global warming impact than a similar amount of emissions of CO₂ or other mobile source GHGs.

In Phase 1, EPA finalized low leakage requirement for all air conditioning systems installed in 2014 model year and later HDVs, with the exception of Class 2b–8 vocational vehicles. As discussed in Section V.B.(2)(c), EPA is extending leakage standards to vocational vehicles for Phase 2. For air conditioning systems with a refrigerant capacity greater than 733 grams, EPA finalized a leakage standard which is a “percent refrigerant leakage per year” to assure that high-quality, low-leakage components are used in each air conditioning system design. EPA finalized a standard of 1.50 percent leakage per year for heavy-duty pickup trucks and vans and Class 7 and 8 tractors. See Section II.E.5. of the Phase 1 Preamble (76 FR 57194–57195) for further discussion of the A/C leakage standard. The leakage standard continues to apply for Phase 2 regardless of the refrigerant used in the A/C system. See Section I.F. for how the Phase 2 program handles the use of alternative refrigerants.

In addition to direct emissions from refrigerant leakage, air conditioning

systems create indirect exhaust emissions due to the extra load on the vehicle's engine to provide power to the air conditioning system. These indirect emissions are in the form of the additional CO₂ emitted from the engine when A/C is being used due to the added loads. Unlike direct emissions which tend to be a set annual leak rate not directly tied to usage, indirect emissions are fully a function of A/C usage. These indirect CO₂ emissions are associated with air conditioner efficiency, since (as just noted) air conditioners create load on the engine. See 74 FR 49529. In Phase 1, the agencies did not set air conditioning efficiency standards for vocational vehicles, combination tractors, or heavy-duty pickup trucks and vans. The CO₂ emissions due to air conditioning systems in these heavy-duty vehicles were estimated to be minimal compared to their overall emissions of CO₂. 76 FR 57194–57196. This continues to be the case. For this reason, EPA did not propose and is not establishing A/C efficiency standards for Phase 2. This differs from light-duty vehicles where CO₂ emissions related to A/C systems can be a significant portion of overall vehicle CO₂ emissions and EPA has established appropriate standards and test procedures.

AAPC and Nissan commented that the agencies should provide A/C efficiency credits similar to those included in the light-duty vehicle program. AAPC also commented that the AC17 test, included in the light-duty vehicle program to confirm A/C system performance, would be impractical and should not be required for heavy-duty vehicles. The agencies did not propose and are not adopting A/C efficiency credits for heavy-duty pickups and vans. AAPC suggests that the agencies could allow the same credits as are available in the light-duty vehicle program but no data is provided regarding the appropriateness of the credits. The EPA would need to resolve a number of open issues relating to environmental implications of A/C efficiency credits for these vehicles (among them, potential credit generation rate, whether credits would be windfall, implications for the standard stringency) before considering adopting an A/C efficiency credit regime. Also, the AC17 test is an integral part of the light-duty vehicle program serving as a confirmation that the credits are based on actual performance improvements. EPA does not believe that it would be appropriate to provide credits based only on the presumption that systems similar to those used in light-duty trucks will

⁴⁶⁸ IPCC AR4 included a N₂O GWP of 298 and a CH₄ GWP of 25. These factors are used in the Phase 1 rule credits calculations.

⁴⁶⁹ The U.S. EPA has reclamation requirements for refrigerants in place under Title VI of the Clean Air Act. See 40 CFR part 82 Subpart B.

provide the same improvements in heavy-duty pickups and vans with no confirmation through testing.

AAPC also recommended that EPA provide credits for reduced refrigerant leakage and alternative refrigerant usage similar to the light-duty vehicle program. In response, as discussed above and in Section I.F, EPA has established standards for refrigerant leakage. EPA does not believe that it would be appropriate to provide credits for items that are essentially required. Providing such credits without an increase in total program stringency similar to the light-duty approach to A/C efficiency and refrigerant leakage would result in a loss of program benefits.

C. Use of the CAFE Model in Heavy-Duty Rulemaking

NHTSA developed the CAFE model in 2002 to support the 2003 issuance of CAFE standards for MYs 2005–2007 light trucks. NHTSA has since significantly expanded and refined the model, and has applied the model to support every ensuing CAFE rulemaking for both light-duty and heavy-duty. For this analysis, the model was reconfigured to use the work based attribute metric of “work factor” established in the Phase 1 rule instead of the light duty “footprint” attribute metric.

Past analyses conducted using the CAFE model have been subjected to extensive and detailed review and comment, much of which has informed the model’s expansion and refinement. NHTSA’s use of the model was considered and supported in *Center for Biological Diversity v. National Highway Traffic Safety Admin.*, 538 F.3d 1172, 1194 (9th Cir. 2008). For further discussion see 76 FR 57198, and the model has been subjected to formal peer review and review by the General Accounting Office (GAO) and National Research Council (NRC). NHTSA makes public the model, source code, and—except insofar as doing so will compromise confidential business information (CBI) manufacturers have provided to NHTSA—all model inputs and outputs underlying published rulemaking analyses.

Although the CAFE model can also be used for more aggregated analysis (e.g., involving “representative vehicles,” single-year snapshots, etc.), NHTSA designed the model with a view toward (a) detailed simulation of manufacturers’ potential actions given a defined set of standards, followed by (b) calculation of resultant impacts and economic costs and benefits. The model is intended to describe actions

manufacturers *could* take in light of defined standards and other input assumptions and estimates, not to predict actions manufacturers *will* take in light of competing product and market interests (e.g. engine power, customer features, technology acceptance, etc.).

For the proposal, the agencies conducted coordinated and complementary analyses using two analytical methods for the heavy-duty pickup and van segment by employing both NHTSA’s CAFE model and EPA’s MOVES model. The agencies used EPA’s MOVES model to estimate fuel consumption and emissions impacts for tractor-trailers (including the engine that powers the tractor), and vocational vehicles (including the engine that powers the vehicle). Additional calculations were performed to determine corresponding monetized program costs and benefits. For heavy-duty pickups and vans, the agencies performed complementary analyses, which we refer to as “Method A” and “Method B.”

For the final rule, NHTSA’s Method A uses a modified version of the CAFE model developed since the NPRM, as well as accompanying updates to CAFE model inputs, to project a pathway the industry could use to comply with each regulatory alternative and the estimated effects on fuel consumption, emissions, benefits and costs were industry to do so. Method A is presented below in Section D and differs from the Method A analysis provided in the NPRM. NHTSA considered the results of the Method A analysis for decision making for the final rule.

EPA’s Method B analysis continues to use the CAFE model and inputs developed for the NPRM to identify technology pathways the industry could potentially use to comply with each regulatory alternative, along with resultant impacts on per vehicle costs should that compliance path be utilized, and the MOVES model was used to calculate corresponding changes in total fuel consumption and annual emissions. The results are presented in Section E. Additional calculations were performed to determine corresponding monetized program costs and benefits. NHTSA’s consideration of the Method A analysis and EPA’s consideration of the Method B analysis led the agencies to the same conclusions regarding the selection of the Phase 2 standards. See Sections D and E for additional discussion of these two methods and the feasibility of the standards.

(1) Overview of the CAFE Model

As a starting point, the model makes use of an input file defining the analysis fleet—that is, a set of specific vehicle models (e.g., Ford F250) and model configurations (e.g., Ford F250 with 6.2-liter V8 engine, 4WD, and 6-speed manual transmission) estimated or assumed to be produced by each manufacturer in each model year to be included in the analysis. The analysis fleet includes key engineering attributes (e.g., curb weight, payload and towing capacities, dimensions, presence of various fuel-saving technologies) of each vehicle model, engine, and transmissions, along with estimates or assumptions of future production volumes. It also specifies the extent to which specific vehicle models share engines, transmissions, and vehicle platforms, and describes each manufacturer’s estimated or assumed product cadence (*i.e.*, timing for freshening and redesigning different vehicles and platforms). This input file also specifies a payback period used to estimate the potential that each manufacturer might apply technology to improve fuel economy beyond levels required by standards.

A second input file to the model contains a variety of contextual estimates and assumptions. Some of these inputs, such as future fuel prices and vehicle survival and mileage accumulation (versus vehicle age), are relevant to estimating manufacturers’ potential application of fuel-saving technologies. Some others, such as fuel density and carbon content, vehicular and upstream emission factors, the social cost of carbon dioxide emissions, and the discount rate, are relevant to calculating physical and economic impacts of manufacturers’ application of fuel-saving technologies.

A third input file contains estimates and assumptions regarding the future applicability, availability, efficacy, and cost of various fuel-saving technologies. Efficacy is expressed in terms of the percentage reduction in fuel consumption, cost is expressed in dollars, and both efficacy and cost are expressed on an incremental basis (*i.e.*, estimates for more advanced technologies are specified as increments beyond less advanced technologies). The input file also includes “synergy factors” used to make adjustments accounting for the potential that some combinations of technologies may result fuel savings or costs different from those indicated by incremental values. Thus, the model itself does not evaluate which technologies will be available, nor does it evaluate how effective or reliable they

will be. The technological availability and effectiveness are rather predefined inputs to the model based on the agencies' judgements and not outputs from the model, which is simply a tool for calculating the effects of combining input assumptions.

Finally, a fourth model input file specifies standards to be evaluated. Standards are defined on a year-by-year basis separately for each regulatory class (passenger cars, light trucks, and heavy-duty pickups and vans). Regulatory alternatives are specified as discrete scenarios, with one scenario defining the no-action alternative or "baseline," all other scenarios defining regulatory alternatives to be evaluated relative to that no-action alternative.

Given these inputs, the model estimates each manufacturer's potential year-by-year application of fuel-saving technologies to each engine, transmission, and vehicle. Subject to a range of engineering and planning-related constraints (*e.g.*, secondary axle disconnect can't be applied to 2-wheel drive vehicles, many major technologies can only be applied practicably as part of a vehicle redesign, and applied technologies carry forward between model years), the model attempts to apply technology to each manufacturer's fleet in a manner that minimizes "effective costs" (accounting, in particular, for technology costs and avoided fuel outlays), continuing to add improvements as long as doing so will help toward compliance with specified standards or will produce fuel savings that "pay back" at least as quickly as specified in the input file mentioned above.

After estimating the extent to which each manufacturer might add fuel-saving technologies under each specified regulatory alternative, the model calculates a range of physical impacts, such as changes in highway travel (*i.e.*, VMT), changes in fleetwide fuel consumption, changes in highway fatalities, and changes in vehicular and upstream greenhouse gas and criteria pollutant emissions. The model also applies a variety of input estimates and assumptions to calculate economic costs and benefits to vehicle owners and society, based on these physical impacts. These are considered Method A results.

Since the manufacturers of HD pickups and vans generally only have one basic pickup truck and van with different versions (*i.e.*, different wheelbases, cab sizes, two-wheel drive, four-wheel drive, etc.) there exists less flexibility than in the light-duty fleet to coordinate model improvements over several years. As such, the CAFE model

allows changes to the HD pickups and vans to meet new standards according to estimated redesign cycles included as a model input. As noted above, the opportunities for large-scale changes (*e.g.*, new engines, transmission, vehicle body and mass) thus occur less frequently than in the light-duty fleet, typically at spans of eight or more years for this analysis. However, opportunities for gradual improvements not necessarily linked to large scale changes can occur between the redesign cycles (*i.e.*, model refresh). Examples of such improvements are upgrades to an existing vehicle model's engine, transmission and aftertreatment systems.

(2) How did the agencies develop the analysis fleet for the NPRM?

As discussed above, both agencies used a version of NHTSA's CAFE modeling system to estimate technology costs and application rates under each regulatory alternative considered. The modeling system relies on many inputs, including an analysis fleet. In order to estimate the impacts of potential standards, it is necessary to estimate the composition of the future vehicle fleet. Doing so enables estimation of the extent to which each manufacturer may need to add technology in response to a given series of attribute-based standards, accounting for the mix and fuel consumption of vehicles in each manufacturer's regulated fleet. The agencies create an analysis fleet in order to track the volumes and types of fuel economy-improving and CO₂-reducing technologies that are already present in the existing vehicle fleet. This aspect of the analysis fleet helps to keep the CAFE model from adding technologies to vehicles that already have these technologies, which will result in "double counting" of technologies' costs and benefits. An additional step involved projecting the fleet sales into MYs 2019–2030. This represents the fleet volumes that the agencies believe will exist in MYs 2019–2030. The following presents an overview of the information and methods applied to develop the analysis fleet, and some basic characteristics of that fleet.

Most of the information about the vehicles that make up the 2014 analysis fleet (used in the NPRM and Method B of this FRM) and the 2015 analysis fleet (used in Method A of this FRM) was gathered from the 2014 and 2015 Pre-Model Year Reports submitted to EPA by the manufacturers under Phase 1 of Fuel Efficiency and GHG Emission Program for Medium- and Heavy-Duty Trucks, MYs 2014–2018. The major manufacturers of class 2b and class 3

trucks (Chrysler, Ford and GM) were asked to voluntarily submit updates to their Pre-Model Year Reports. The agencies used these updated data in constructing the analysis fleet for these manufacturers. The agencies agreed to treat this information as Confidential Business Information (CBI) until the publication of the proposed rule. This information can be made public at this time because by now all MY 2014 and MY 2015 vehicle models have been produced, which makes data about them essentially public information.

In addition to information about each vehicle, the agencies need additional information about the fuel economy-improving/CO₂-reducing technologies already on those vehicles in order to assess how much and which technologies to apply to determine a path toward future compliance. To correctly account for the cost and effectiveness of adding technologies, it is necessary to know the technology penetration in the existing vehicle fleet. Otherwise, "double-counting" of technology could occur. Thus, in their respective analysis fleets, the agencies augmented this information with data from public and commercial sources⁴⁷⁰ that include more complete technology descriptions, *e.g.* for specific engines and transmissions.

The resultant analysis fleets are provided in detail at NHTSA's Web site, along with all other inputs to and outputs from both the NPRM and the current analysis. The agencies invited but did not receive comment on this analysis.

(a) Vehicle Redesign Schedules and Platforms

Product cadence in the Class 2b and 3 pickup market has historically ranged from 7–9 years between major redesigns. However, due to increasing competitive pressures and consumer demands the agency anticipates that manufacturers will generally shift to shorter design cycles resembling those of the light duty market. Pickup truck manufacturers in the Class 2b and 3 segments are shown to adopt redesign cycles of six years, allowing two redesigns prior to the end of the regulatory period in 2025.

The Class 2b and 3 van market has changed markedly from five years ago. Ford, Nissan, Ram and Daimler have adopted vans of "Euro Van" appearance, and in many cases now use smaller turbocharged gasoline or diesel engines in the place of larger, naturally-aspirated V8s. The 2014 and 2015 model years used in this analysis

⁴⁷⁰ *e.g.*, manufacturers' Web sites, Wards Automotive.

represent a period where most manufacturers, with the exception of General Motors, have recently introduced a completely redesigned product after many years. The van segment has historically been one of the slowest to be redesigned of any product segment, with some products going two decades or more between redesigns.

Due to new entrants in the field and increased competition, the agencies anticipate that most manufacturers will increase the pace of product redesigns in the van segment, but that they will continue to trail other segments. The cycle time used in this analysis is approximately ten years between major redesigns, allowing manufacturers' only one major redesign during the regulatory period. The agencies did not receive comment on this anticipated product design cycle.

Additional detail on product cadence assumptions for specific manufacturers is located in Chapter 10 of the RIA.

(b) Sales Volume Forecast

Since each manufacturer's required average fuel consumption and GHG levels are sales-weighted averages of the fuel economy/GHG targets across all model offerings, sales volumes play a critical role in estimating that burden. The CAFE model requires a forecast of sales volumes, at the vehicle model-variant level, in order to simulate the

technology application necessary for a manufacturer to achieve compliance in each model year for which outcomes are simulated.

As stated above, the agencies relied on the pre-model-year compliance submissions from manufacturers to provide sales volumes at the model level based on the level of disaggregation in which the models appear in the compliance data. However, the agencies only use these reported volumes without adjustment for the reference fleet model year (MY 2014 or MY 2015). For all future model years, we combine the manufacturer submissions with sales projections from the 2014 (for the NPRM and Method B of the FRM) or 2015 (for Method A of the FRM) Annual Energy Outlook Reference Case and IHS Automotive to determine model variant level sales volumes in future years.⁴⁷¹ The projected sales volumes by class that appear in the Annual Energy Outlook as a result of a collection of assumptions about economic conditions, demand for commercial miles traveled, and technology migration from light-duty pickup trucks in response to the concurrent light-duty CAFE/GHG standards. These are shown in Chapter 2 of the RIA.

The projection of total sales volumes for the Class 2b and 3 market segment

was based on the total volumes in the 2014 AEO Reference Case in the NPRM and for Method B of this FRM. For the purposes of this analysis, the AEO2014 calendar year volumes have been used to represent the corresponding model-year volumes. While AEO2014 provides enough resolution in its projections to separate the volumes for the Class 2b and 3 segments, the agencies deferred to the vehicle manufacturers and chose to rely on the relative shares present in the pre-model-year compliance data. This methodology remains the same for the Method A FRM analysis, but we have replaced the 2014 AEO reference case with the 2015 AEO reference case.

The relative sales share by vehicle type (van or pickup truck, in this case) was derived from a sales forecast that the agencies purchased from IHS Automotive, and applied to the total volumes in the AEO2014 projection. Table VI-3 shows the implied shares of the total new 2b/3 vehicle market broken down by manufacturer and vehicle type. The same methodology was applied using 2015 IHS/Polk projections, and the total volumes from the AEO2015 projection for Method A of the FRM. The results of the 2015-based projections are presented in the following section about changes made to the model since the NPRM.

TABLE VI-3—IHS AUTOMOTIVE MARKET SHARE FORECAST FOR 2B/3 VEHICLES

Manufacturer	Style	Model year market share						
		2015 (%)	2016 (%)	2017 (%)	2018 (%)	2019 (%)	2020 (%)	2021 (%)
Daimler	Van	3	3	3	3	3	3	3
Fiat Chrysler	Van	2	2	2	2	2	2	3
Ford	Van	16	17	17	17	18	18	18
General Motors	Van	12	12	11	12	13	13	13
Nissan	Van	2	2	2	2	2	2	2
Daimler	Pickup	0	0	0	0	0	0	0
Fiat Chrysler	Pickup	14	14	14	14	11	12	12
Ford	Pickup	28	27	30	30	30	27	26
General Motors	Pickup	23	23	21	21	21	22	23
Nissan	Pickup	0	0	0	0	0	0	0

Within those broadly defined market shares, volumes at the manufacturer/model-variant level were constructed by applying the model-variant's share of manufacturer sales in the pre-model-year compliance data for the relevant vehicle style, and multiplied by the total volume estimated for that manufacturer and that style.

After building out a set of initial future sales volumes based on the sources described above, the agencies

attempted to incorporate new information about changes in sales mix that are not captured by either the existing sales forecasts or the simulated technology changes in vehicle platforms. In particular, Ford has announced intentions to phase out their existing Econoline vans, gradually shifting volumes to the new Transit platform for some model variants (notably chassis cabs and cutaways

variants) and eliminating offerings outright for complete Econoline vans as early as model year 2015. In the case of complete Econoline vans, the volumes for those vehicles were allocated to MY 2015 Transit vehicles based on assumptions about likely production splits for the powertrains of the new Transit platform. The volumes for complete Econoline vans were shifted at ratios of 50 percent, 35 percent, and 15

⁴⁷¹ Tables from AEO's forecast are available at <http://www.eia.gov/oiaf/aeo/tablebrowser/>. The

agencies also made use of the IHS Automotive Light Vehicle Production Forecast (August 2014).

percent for 3.7 L, 3.5 L Eco-boost, and 3.2 L diesel, respectively. Within each powertrain, sales were allocated based on the percentage shares present in the pre-model-year compliance data. The chassis cab and cutaway variants of the Econolines were phased out linearly between MY 2015 and MY 2020, at which time the Econolines cease to exist in any form and all corresponding volume resides with the Transits.

(3) Other Analysis Inputs

In addition to the inputs summarized above, the analysis of potential standards for HD pickups and vans makes use of a range of other estimates and assumptions specified as inputs to the CAFE modeling system. Some significant inputs (*e.g.*, estimates of future fuel prices) also applicable to other MDHD segments are discussed below in Section IX. Others more specific to the analysis of HD pickups and vans are as follows:

(a) Vehicle Survival and Mileage Accumulation

The analysis estimates the travel, fuel consumption, and emissions over the useful lives of vehicles produced during model years 2014–2030. Doing so requires initial estimates of these vehicles' survival rates (*i.e.*, shares expected to remain in service) and mileage accumulation rates (*i.e.*, anticipated annual travel by vehicles remaining in service), both as a function of vehicle vintage (*i.e.*, age). These estimates are based on an empirical analysis of changes in the fleet of registered vehicles over time from HIS/Polk data, in the case of survival rates. The NPRM and Method A of the FRM use data collected as part of the last Vehicle In Use Survey (the 2002 VIUS) for the mileage accumulation schedule. Method A of the FRM uses mileage accumulation schedules from 2014 Polk/IHS odometer reading data. The changes to the VMT schedules for Method A of the current analysis are further described below in the Method A FRM specific changes.

(b) Rebound Effect

Expressed as an elasticity of mileage accumulation with respect to the fuel cost per mile of operation, the agencies have applied a rebound effect of 10 percent for today's analysis. Other rebound effects are considered in sensitivity analyses in Sections D.

(c) On-Road "Gap"

The model was run with a 20 percent adjustment to reflect differences between on-road and laboratory performance.

(d) Fleet Population Profile

Though not reported here, cumulative fuel consumption and CO₂ emissions are presented in the accompanying EIS, and these calculations utilize estimates of the numbers of vehicles produced in each model year remaining in service in calendar year 2014. The initial age distribution of the registered vehicle population in 2014 is based on vehicle registration data acquired by NHTSA from R.L. Polk Company. For Method A, these values were updated to reflect newer data acquired by NHTSA from Polk.

(e) Past Fuel Consumption Levels

Though not reported here, cumulative fuel consumption and CO₂ emissions are presented in the accompanying EIS, and these calculations require estimates of the performance of vehicles produced prior to model year 2014. Consistent with AEO 2014, the model was run with the assumption that gasoline and diesel HD pickups and vans averaged 14.9 mpg and 18.6 mpg, respectively, with gasoline versions averaging about 48 percent of production. For Method A, these values were updated to reflect AEO2015, such that gasoline and diesel versions were projected to average 16.0 mpg and 20.0 mpg, respectively.

(f) Long-Term Fuel Consumption Levels

Though not reported here, longer-term estimates of fuel consumption and emissions are presented in the accompanying EIS. These estimates include calculations involving vehicle produced after MY 2030 and, consistent with AEO 2014, the model was run with the assumption that fuel consumption and CO₂ emission levels will continue to decline at 0.05 percent annually (compounded) after MY 2030.

(g) Payback Period

To estimate in what sequence and to what degree manufacturers might add fuel-saving technologies to their respective fleets, the CAFE model iteratively ranks remaining opportunities (*i.e.*, applications of specific technologies to specific vehicles) in terms of effective cost, primary components of which are the technology cost and the avoided fuel outlays, attempting to minimize effective costs incurred.⁴⁷² Depending on inputs, the model also assumes manufacturers may improve fuel consumption beyond requirements insofar as doing so will involve applications of technology at negative effective cost—*i.e.*, technology

application for which buyers' up-front costs are quickly paid back through avoided fuel outlays. This calculation includes only fuel outlays occurring within a specified payback period. For both Method A and Method B, a payback period of 6 months was applied for the dynamic baseline case, or Alternative 1b. Thus, for example, a manufacturer already in compliance with standards is projected to apply a fuel consumption improvement projected to cost \$250 (*i.e.*, as a cost that could be charged to the buyer at normal profit to the manufacturer) and reduce fuel costs by \$500 in the first year of vehicle operation. The agencies have conducted the same analysis applying a payback period of 0 months for the flat baseline case, or Alternative 1a. For Method A, Alternative 1b is the primary analysis, and Alternative 1a is one of a range of cases included in the sensitivity analysis.

(h) Civil Penalties in the NHTSA Analysis

EPCA and EISA require that a manufacturer pay civil penalties if it does not have enough credits to cover a shortfall with one or both of the light-duty CAFE standards in a model year. While these provisions do not apply to HD pickups and vans, at this time, the CAFE model will show civil penalties owed in cases where available technologies and credits are estimated to be insufficient for a manufacturer to achieve compliance with a standard. These model-reported estimates have been excluded from this analysis. For Method A, this aspect of the model has been modified to also exclude from the calculation of "effective cost" used to select among available options to add specific technologies to specific vehicles.

(i) Coefficients for Fatality Calculations

Both the NPRM and the current analysis consider the potential effects on crash safety of the technologies manufacturers may apply to their vehicles to meet each of the regulatory alternatives. NHTSA research has shown that vehicle mass reduction affects overall societal fatalities associated with crashes⁴⁷³ and, most relevant to this rule, mass reduction in heavier light- and medium-duty vehicles has an overall beneficial effect on societal fatalities. Reducing the mass of a heavier vehicle involved in a crash with another vehicle(s) makes it less

⁴⁷² Volpe CAFE Model, available at <http://www.nhtsa.gov/fuel-economy>.

⁴⁷³ U.S. DOT/NHTSA, *Relationships Between Fatality Risk Mass and Footprint in MY 2000–2007 PC and LTVs*, ID: NHTSA–2010–0131–0336, Posted August 21, 2012.

likely there will be fatalities among the occupants of the other vehicles. In addition to the effects of mass reduction, the analysis anticipates that these standards, by reducing the cost of driving HD pickups and vans, will lead to increased travel by these vehicles and, therefore, more crashes involving these vehicles. The Method B analysis considers overall impacts considering both of these factors, using a methodology similar to NHTSA's analyses for the MYs 2017–2025 CAFE and GHG emission standards.

The Method B analysis includes estimates of the extent to which HD pickups and vans produced during MYs 2014–2030 may be involved in fatal crashes, considering the mass, survival, and mileage accumulation of these vehicles, taking into account changes in mass and mileage accumulation under each regulatory alternative. These calculations make use of the same coefficients applied to light trucks in the MYs 2017–2025 CAFE rulemaking analysis. Baseline rates of involvement in fatal crashes are 13.03 and 13.24 fatalities per billion miles for vehicles with initial curb weights above and below 4,594 lbs, respectively. Considering that the data underlying the corresponding statistical analysis included observations through calendar year 2010, these rates are reduced by 9.6 percent to account for subsequent impacts of recent Federal Motor Vehicle Safety Standards (FMVSS) and anticipated behavioral changes (e.g., continued increases in seat belt use). For vehicles above 4,594 lbs—i.e., the majority of the HD pickup and van fleet—mass reduction is estimated to reduce the net incidence of highway fatalities by 0.34 percent per 100 lbs. of removed curb weight. For the few HD pickups and vans below 4,594 lbs, mass reduction is estimated to increase the net incidence of highway fatalities by 0.52 percent per 100 lbs. Consistent with DOT guidance, the social cost of highway fatalities is estimated using a value of statistical life (VSL) of \$9.36m in 2014, increasing thereafter at 1.18 percent annually.

The Method A analysis uses the same methodology as described above, but applies coefficients that have been updated to reflect more current data, updated statistical analysis by NHTSA staff, and updated DOT guidance regarding the VSL. Baseline rates of involvement in fatal crashes are 16.06 and 14.35 fatalities per billion miles for pickups and vans with initial curb weights above and below 4,947 lbs, respectively. Considering that the data underlying the corresponding statistical analysis included observations through

calendar year 2012, these rates are reduced by 9.6 percent to account for subsequent impacts of recent Federal Motor Vehicle Safety Standards (FMVSS) and anticipated behavioral changes (e.g., continued increases in seat belt use). For vehicles above 4,947 lbs—i.e., the majority of the HD pickup and van fleet—mass reduction is estimated to reduce the net incidence of highway fatalities by 0.72 percent per 100 lbs. of removed curb weight. For HD pickups and vans below 4,947 lbs (accounting for any applied mass reduction), mass reduction is estimated to reduce the net incidence of highway fatalities by 0.10 percent per 100 lbs. Consistent with DOT guidance, the social cost of highway fatalities is estimated using a value of statistical life (VSL) of \$9.4m from 2015 forward.

(j) Compliance Credit Provisions

Today's analysis accounts for the potential to over comply with standards and thereby earn compliance credits, applying these credits to ensuring compliance requirements. In doing so, the agencies treat any unused carried-forward credits as expiring after five model years, consistent with current and standards. For today's analysis, the agencies are not estimating the potential to “borrow”—i.e., to carry credits back to past model years.

(k) Emission Factors

While CAFE model calculates vehicular CO₂ emissions directly on a per-gallon basis using fuel consumption and fuel properties (density and carbon content), the model calculates emissions of other pollutants (methane, nitrogen oxides, ozone precursors, carbon monoxide, sulfur dioxide, particulate matter, and air toxics) on a per-mile basis. In doing so, the Method A analysis used corresponding emission factors estimated using EPA's MOVES model.⁴⁷⁴ To estimate emissions (including CO₂) from upstream processes involved in producing, distributing, and delivering fuel, NHTSA has applied emission factors—all specified on a gram per gallon basis—derived from Argonne National Laboratory's GREET model.⁴⁷⁵

(l) Refueling Time Benefits

To estimate the value of time savings associated with vehicle refueling, the Method A analysis used estimates that

an average refueling event involves refilling 60 percent of the tank's capacity over the course of 3.5 minutes, at an hourly cost of \$27.22.

(m) External Costs of Travel

Changes in vehicle travel will entail economic externalities. To estimate these costs, the Method A analysis used estimates that congestion-, crash-, and noise-related externalities will total 5.1¢/mi., 2.8¢/mi., and 0.1¢/mi., respectively.

(n) Ownership and Operating Costs

Method A results predict that the total cost of vehicle ownership and operation will change not just due to changes in vehicle price and fuel outlays, but also due to some other costs likely to vary with vehicle price. To estimate these costs, NHTSA has applied factors of 5.5 percent (of price) for taxes and fees, 15.3 percent for financing, 19.2 percent for insurance, 1.9 percent for relative value loss. The Method A analysis also estimates that average vehicle resale value will increase by 25 percent of any increase in new vehicle price.

(4) What Technologies Did the Agencies Consider

The agencies considered over 35 vehicle technologies that manufacturers could use to improve the fuel consumption and reduce CO₂ emissions of their vehicles during MYs 2021–2027. The majority of the technologies described in this section are readily available, well known and proven in other vehicle sectors, and could be incorporated into vehicles once production decisions are made. Other technologies considered may not currently be in production, but are beyond the research phase and under development, and are expected to be in production in highway vehicles over the next few years. These are technologies that are capable of achieving significant improvements in fuel economy and reductions in CO₂ emissions, at reasonable costs. The agencies did not consider technologies in the research stage because there is insufficient time for such technologies to move from research to production during the model years covered by this final action.

The technologies considered in the agencies' analysis are briefly described below. They fall into five broad categories: Engine technologies, transmission technologies, vehicle technologies, electrification/accessory technologies, and hybrid technologies.

In this class of trucks and vans, diesel engines are installed in about half of all vehicles. The buyer's decision to purchase a diesel versus gasoline engine

⁴⁷⁴ EPA MOVES model available at <http://www3.epa.gov/otaq/models/moves/index.htm> (last accessed Feb 23, 2015).

⁴⁷⁵ GREET (Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation) Model, Argonne National Laboratory, <https://greet.es.anl.gov/>.

depends on several factors including initial purchase price, fuel operating costs, durability, towing capability and payload capacity amongst other reasons. As discussed in VI.B. above, the agencies generally prefer to set standards that do not distinguish between fuel types where technological or market-based reasons do not strongly argue otherwise. However, as with Phase 1, we continue to believe that fundamental differences between spark ignition and compression ignition engines warrant unique fuel standards, which is also important in ensuring that our program maintains product choices available to vehicle buyers. Therefore, as discussed in Section B.1, we are maintaining separate standards for gasoline and diesel vehicles. In the context of our technology discussion for heavy-duty pickups and vans, we are treating gasoline and diesel engines separately so each has a set of baseline technologies. We discuss performance improvements in terms of changes to those baseline engines. Our cost and inventory estimates contained elsewhere reflect the current fleet baseline with an appropriate mix of gasoline and diesel engines. Note that we are not basing these standards on a targeted switch in the mix of diesel and gasoline vehicles. We believe our standards require similar levels of technology development and cost for both diesel and gasoline vehicles. Hence the program is not intended to force, nor discourage, changes in a manufacturer's fleet mix between gasoline and diesel vehicles.

The following contains a description of technologies the agencies considered as potentially available in the rule timeframe, and hence, having potential to be part of a compliance pathway for these vehicles. Additionally, the agencies did not receive any comments indicating that the technology effectiveness estimates used in the determination of potential reductions in GHGs and fuel consumption are not representative of the expected ranges for expected duty cycles.

(a) Engine Technologies

The agencies reviewed the engine technology estimates used in the 2017–2025 light-duty rule, the 2014–2018 heavy-duty rule, and the 2015 NHTSA Technology Study. In doing so the agencies reconsidered all available sources and updated the estimates as appropriate. The section below describes both diesel and gasoline engine technologies considered for this program.

(i) Low Friction Lubricants

One of the most basic methods of reducing fuel consumption in both gasoline and diesel engines is the use of lower viscosity engine lubricants. More advanced multi-viscosity engine oils are available today with improved performance in a wider temperature band and with better lubricating properties. This can be accomplished by changes to the oil base stock (*e.g.*, switching engine lubricants from a Group I base oils to lower-friction, lower viscosity Group III synthetic) and through changes to lubricant additive packages (*e.g.*, friction modifiers and viscosity improvers). The use of 5W–30 motor oil is now widespread and auto manufacturers are introducing the use of even lower viscosity oils, such as 5W–20 and 0W–20, to improve cold-flow properties and reduce cold start friction. However, in some cases, changes to the crankshaft, rod and main bearings and changes to the mechanical tolerances of engine components may be required. In all cases, durability testing will be required to ensure that durability is not compromised. The shift to lower viscosity and lower friction lubricants will also improve the effectiveness of valvetrain technologies such as cylinder deactivation, which rely on a minimum oil temperature (viscosity) for operation.

(ii) Engine Friction Reduction

In addition to low friction lubricants, manufacturers can also reduce friction and improve fuel consumption by improving the design of both diesel and gasoline engine components and subsystems. Approximately 10 percent of the energy consumed by a vehicle is lost to friction, and just over half is due to frictional losses within the engine.⁴⁷⁶ Examples include improvements in low-tension piston rings, piston skirt design, roller cam followers, improved crankshaft design and bearings, material coatings, material substitution, more optimal thermal management, and piston and cylinder surface treatments. Additionally, as computer-aided modeling software continues to improve, more opportunities for evolutionary friction reductions may become available. All reciprocating and rotating components in the engine are potential candidates for friction

⁴⁷⁶ "Impact of Friction Reduction Technologies on Fuel Economy," Fenske, G. Presented at the March 2009 Chicago Chapter Meeting of the 'Society of Tribologists and Lubricated Engineers' Meeting, March 18th, 2009. Available at: <http://www.chicagostle.org/program/2008-2009/Impact%20of%20Friction%20Reduction%20Technologies%20on%20Fuel%20Economy%20-%20with%20VGs%20removed.pdf> (last accessed July 9, 2009).

reduction, and minute improvements in several components can add up to a measurable fuel efficiency improvement.

(iii) Engine Parasitic Demand Reduction

In addition to physical engine friction reduction, manufacturers can reduce the mechanical load on the engine from parasitics, such as oil, fuel, and coolant pumps. The high-pressure fuel pumps of direct-injection gasoline and diesel engines have particularly high demand. Example improvements include variable speed or variable displacement water pumps, variable displacement oil pumps, more efficient high pressure fuel pumps, valvetrain upgrades and shutting off piston cooling when not needed.

(iv) Coupled Cam Phasing

Valvetrains with coupled (or coordinated) cam phasing can modify the timing of both the inlet valves and the exhaust valves an equal amount by phasing the camshaft of an overhead valve engine.⁴⁷⁷ For overhead valve engines, which have only one camshaft to actuate both inlet and exhaust valves, couple cam phasing is the only variable valve timing (VVT) implementation option available and requires only one cam phaser.⁴⁷⁸ We also considered variable valve lift (VVL), which alters the intake valve lift in order to reduce pumping losses and more efficiently ingest air.

(v) Cylinder Deactivation

In conventional spark-ignited engines throttling the airflow controls engine torque output. At partial loads, efficiency can be improved by using cylinder deactivation instead of throttling. Cylinder deactivation can improve engine efficiency by disabling or deactivating (usually) half of the cylinders when the load is less than half of the engine's total torque capability—the valves are kept closed, and no fuel is injected—as a result, the trapped air within the deactivated cylinders is simply compressed and expanded as an air spring, with reduced friction and

⁴⁷⁷ Although couple cam phasing appears only in the single overhead cam and overhead valve branches of the decision tree, it is noted that a single phaser with a secondary chain drive would allow couple cam phasing to be applied to direct overhead cam engines. Since this would potentially be adopted on a limited number of direct overhead cam engines NHTSA did not include it in that branch of the decision tree.

⁴⁷⁸ It is also noted that coaxial camshaft developments would allow other variable valve timing options to be applied to overhead valve engines. However, since they would potentially be adopted on a limited number of overhead valve engines, NHTSA did not include them in the decision tree.

heat losses. The active cylinders combust at almost double the load required if all of the cylinders were operating. Pumping losses are significantly reduced as long as the engine is operated in this “part-cylinder” mode.

Cylinder deactivation control strategy relies on setting maximum manifold absolute pressures or predicted torque within a range in which it can deactivate the cylinders. Noise and vibration issues reduce the operating range to which cylinder deactivation is allowed, although manufacturers are exploring vehicle changes that enable increasing the amount of time that cylinder deactivation might be suitable. Some manufacturers may choose to adopt active engine mounts and/or active noise cancellations systems to address Noise Vibration and Harshness (NVH) concerns and to allow a greater operating range of activation.

Cylinder deactivation has seen a recent resurgence thanks to better valvetrain designs and engine controls. General Motors and Fiat Chrysler have incorporated cylinder deactivation across a substantial portion of their V8-powered lineups, including some heavy duty applications.

(vi) Stoichiometric Gasoline Direct Injection

SGDI engines inject fuel at high pressure directly into the combustion chamber (rather than the intake port in port fuel injection). SGDI requires changes to the injector design, an additional high pressure fuel pump, new fuel rails to handle the higher fuel pressures and changes to the cylinder head and piston crown design. Direct injection of the fuel into the cylinder improves cooling of the air/fuel charge within the cylinder, which allows for higher compression ratios and increased thermodynamic efficiency without the onset of combustion knock. Recent injector design advances, improved electronic engine management systems and the introduction of multiple injection events per cylinder firing cycle promote better mixing of the air and fuel, enhance combustion rates, increase residual exhaust gas tolerance and improve cold start emissions. SGDI engines achieve higher power density and match well with other technologies, such as boosting and variable valvetrain designs.

Most manufacturers have introduced vehicles with SGDI engines in light duty sectors, including GM and Ford and have announced their plans to increase dramatically the number of SGDI engines in their portfolios. SGDI has not been introduced on heavy duty

applications at this time however as these largely dedicated heavy duty engines approach their redesign window, they are expected to become SGDI engines.

(vii) Turbocharging and Downsizing

The specific power of a naturally aspirated engine is primarily limited by the rate at which the engine is able to draw air into the combustion chambers. Turbocharging and supercharging (grouped together here as boosting) are two methods to increase the intake manifold pressure and cylinder charge-air mass above naturally aspirated levels. Boosting increases the airflow into the engine, thus increasing the specific power level, and with it the ability to reduce engine displacement while maintaining performance. This effectively reduces the pumping losses at lighter loads in comparison to a larger, naturally aspirated engine.

Almost every major manufacturer currently markets a vehicle with some form of boosting. While boosting has been a common practice for increasing performance for several decades, turbocharging has considerable potential to improve fuel economy and reduce CO₂ emissions when the engine displacement is also reduced. Specific power levels for a boosted engine often exceed 100 hp/L, compared to average naturally aspirated engine power densities of roughly 70 hp/L. As a result, engines can be downsized roughly 30 percent or higher while maintaining similar peak output levels. In the last decade, improvements to turbocharger turbine and compressor design have improved their reliability and performance across the entire engine operating range. New variable geometry turbines and ball-bearing center cartridges allow faster turbocharger spool-up (virtually eliminating the once-common “turbo lag”) while maintaining high flow rates for increased boost at high engine speeds. Low speed torque output has been dramatically improved for modern turbocharged engines. However, even with turbocharger improvements, maximum engine torque at very low engine speed conditions, for example launch from standstill, is increased less than at mid and high engine speed conditions. The potential to downsize engines may be less on vehicles with low displacement to vehicle mass ratios for example a very small displacement engine in a vehicle with significant curb weight, in order to provide adequate acceleration from standstill, particularly up grades or at high altitudes.

The use of GDI in combination with turbocharging and charge air cooling

reduces the fuel octane requirements for knock limited combustion enabling the use of higher compression ratios and boosting pressures. Recently published data with advanced spray-guided injection systems and more aggressive engine downsizing targeted towards reduced fuel consumption and CO₂ emissions reductions indicate that the potential for reducing CO₂ emissions for turbocharged, downsized GDI engines may be as much as 15 to 30 percent relative to port-fuel-injected engines.^{14 15 16 17 18} Confidential manufacturer data suggests an incremental range of fuel consumption and CO₂ emission reduction of 4.8 to 7.5 percent for turbocharging and downsizing. Other publicly-available sources suggest a fuel consumption and CO₂ emission reduction of 8 to 13 percent compared to current-production naturally-aspirated engines without friction reduction or other fuel economy technologies: A joint technical paper by Bosch and Ricardo suggesting fuel economy gain of 8 to 10 percent for downsizing from a 5.7 liter port injection V8 to a 3.6 liter V6 with direct injection using a wall-guided direct injection system; a Renault report suggesting a 11.9 percent NEDC fuel consumption gain for downsizing from a 1.4 liter port injection in-line 4-cylinder engine to a 1.0 liter in-line 4-cylinder engine, also with wall-guided direct injection; and a Robert Bosch paper suggesting a 13 percent NEDC gain for downsizing to a turbocharged DI engine, again with wall-guided injection. These reported fuel economy benefits show a wide range depending on the SGDI technology employed.

Note that for this analysis the agencies determined that this technology path is only applicable to heavy duty applications that have operating conditions more closely associated with light duty vehicles. This includes vans designed mainly for cargo volume or modest payloads and having similar GCWR to light duty applications. These vans cannot tow trailers heavier than similar light duty vehicles and are largely already sharing engines of significantly smaller displacement and cylinder count compared to heavy duty vehicles designed mainly for trailer towing.

ACEEE commented that 10 percent of pick-ups in the heavy duty sector are candidates for turbocharging and downsizing if they do not require higher payloads or towing capacity. Other commenters suggested that downsizing that has occurred in light duty could also occur in heavy duty. As discussed above, the agencies evaluated turbocharging and downsizing in

vehicles like vans which are not typically designed for extensive trailer towing. When we looked at pick-ups, we determined that consumers needing a pick-up without higher payload or trailer towing requirements would migrate to the lower cost light-duty versions which are typically identical in cabin size and seating as the heavy-duty versions but have less work capability. Because of this, in the agencies' assessment, the heavy-duty pickups retained the high trailer towing and payload requirements and the corresponding larger engines. AAPC comments supported this approach as the correct combination of engine to intended use and even provided in their comments data indicating that turbocharged and downsized engines are more fuel efficient at lighter loads however under working conditions expected of a heavy-duty pick-up they are actually less fuel efficient than the larger engines.

(viii) Cooled Exhaust-Gas Recirculation

Cooled exhaust gas recirculation or Boosted EGR is a combustion concept that involves utilizing EGR as a charge diluent for controlling combustion temperatures and cooling the EGR prior to its introduction to the combustion system. Higher exhaust gas residual levels at part load conditions reduce pumping losses for increased fuel economy. The additional charge dilution enabled by cooled EGR reduces the incidence of knocking combustion and obviates the need for fuel enrichment at high engine power. This allows for higher boost pressure and/or compression ratio and further reduction in engine displacement and both pumping and friction losses while maintaining performance. Engines of this type use GDI and both dual cam phasing and discrete variable valve lift. The EGR systems considered in this final rule, consistent with the rule, will use a dual-loop system with both high and low pressure EGR loops and dual EGR coolers. The engines will also use single-stage, variable geometry turbocharging with higher intake boost pressure available across a broader range of engine operation than conventional turbocharged SI engines. Such a system is estimated to be capable of an additional 3 to 5 percent effectiveness relative to a turbocharged, downsized GDI engine without cooled-EGR. The agencies have also considered a more advanced version of such a cooled EGR system that employs very high combustion pressures by using dual stage turbocharging.

(ix) Lean-Burn Combustion

The agencies considered the concept that gasoline engines that are normally stoichiometric mainly for emission reasons can run lean over a range of operating conditions and utilize diesel like aftertreatment systems to control NO_x. For this analysis, we determined that the modal operation nature of this technology is currently only beneficial at light loads and will not be appropriate for a heavy duty application purchase specifically for its high work and load capacity.

(b) Diesel Engine Technologies

Diesel engines have several characteristics that give them superior fuel efficiency compared to conventional gasoline, spark-ignited engines. Pumping losses are much lower due to lack of (or greatly reduced) throttling. The diesel combustion cycle operates at a higher compression ratio, with a very lean air/fuel mixture, and turbocharged light-duty diesels typically achieve much higher torque levels at lower engine speeds than equivalent-displacement naturally-aspirated gasoline engines. Additionally, diesel fuel has a higher energy content per gallon.⁴⁷⁹ However, diesel fuel also has a higher carbon to hydrogen ratio, which increases the amount of CO₂ emitted per gallon of fuel used by approximately 15 percent over a gallon of gasoline.

Based on confidential business information and the 2010 NAS Report, two major areas of diesel engine design could be improved during the timeframe of this final rule. These areas include aftertreatment improvements and a broad range of engine improvements.

(i) Aftertreatment Improvements

The HD diesel pickup and van segment has largely adopted the SCR type of aftertreatment system to comply with criteria pollutant emission standards. As the experience base for SCR expands over the next few years, many improvements in this aftertreatment system such as construction of the catalyst, thermal management, and reductant optimization may result in a reduction in the amount of fuel used in the process. However, due to uncertainties with these improvements regarding the extent of current optimization and future criteria emissions obligations, the agencies are not considering aftertreatment improvements as a fuel-

saving technology in the rulemaking analysis.

(ii) Engine Improvements

Diesel engines in the HD pickup and van segment are expected to have several improvements in their base design in the 2021–2027 timeframe. These improvements include items such as improved combustion management, optimal turbocharger design, and improved thermal management.

(c) Transmission Technologies

The agencies have also reviewed the transmission technology estimates used in the 2017–2015 light-duty and 2014–2018 heavy-duty final rules. In doing so, NHTSA and EPA considered or reconsidered all available sources including the 2015 NHTSA Technology Study and updated the estimates as appropriate. The section below describes each of the transmission technologies considered for this rule.

(i) Automatic 8-Speed Transmissions

Manufacturers can also choose to replace 6-speed automatic transmissions with 8-speed automatic transmissions. Additional ratios allow for further optimization of engine operation over a wider range of conditions, but this is subject to diminishing returns as the number of speeds increases. As additional gear sets are added, additional weight and friction are introduced requiring additional countermeasures to offset these losses. Some manufacturers are replacing 6-speed automatics already, and 7 to 10-speed automatics have entered production.

(ii) High Efficiency Transmission

For this rule, a high efficiency transmission refers to some or all of a suite of incremental transmission improvement technologies that should be available within the 2019 to 2027 timeframe. The majority of these improvements address mechanical friction within the transmission. These improvements include but are not limited to: Shifting clutch technology improvements, improved kinematic design, dry sump lubrication systems, more efficient seals, bearings and clutches (reducing drag), component superfinishing and improved transmission lubricants.

(iii) Secondary Axle Disconnect

The ability to disconnect some of the rotating components in the front axle on 4wd vehicles when the secondary axle is not needed for traction. This will reduce friction and increase fuel economy.

⁴⁷⁹ Burning one gallon of diesel fuel produces about 15 percent more carbon dioxide than gasoline due to the higher density and carbon to hydrogen ratio.

(d) Electrification/Accessory Technologies

(i) Electrical Power Steering or Electrohydraulic Power Steering

Electric power steering (EPS) or Electrohydraulic power steering (EHPS) provides a potential reduction in CO₂ emissions and fuel consumption over hydraulic power steering because of reduced overall accessory loads. This eliminates the parasitic losses associated with belt-driven power steering pumps which consistently draw load from the engine to pump hydraulic fluid through the steering actuation systems even when the wheels are not being turned. EPS is an enabler for all vehicle hybridization technologies since it provides power steering when the engine is off. EPS may be implemented on most vehicles with a standard 12V system. Some heavier vehicles may require a higher voltage system which may add cost and complexity.

(ii) Improved Accessories

The accessories on an engine, including the alternator, coolant and oil pumps are traditionally mechanically-driven. A reduction in CO₂ emissions and fuel consumption can be realized by driving them electrically, and only when needed (“on-demand”).

Electric water pumps and electric fans can provide better control of engine cooling. For example, coolant flow from an electric water pump can be reduced and the radiator fan can be shut off during engine warm-up or cold ambient temperature conditions which will reduce warm-up time, reduce warm-up fuel enrichment, and reduce parasitic losses.

Indirect benefit may be obtained by reducing the flow from the water pump electrically during the engine warm-up period, allowing the engine to heat more rapidly and thereby reducing the fuel enrichment needed during cold operation and warm-up of the engine. Faster oil warm-up may also result from better management of the coolant warm-up period. Further benefit may be obtained when electrification is combined with an improved, higher efficiency engine alternator used to supply power to the electrified accessories.

Intelligent cooling can more easily be applied to vehicles that do not typically carry heavy payloads, so larger vehicles with towing capacity present a challenge, as these vehicles have high cooling fan loads.⁴⁸⁰ However, towing vehicles tend to have large cooling

system capacity and flow scaled to required heat rejection levels when under full load situations such as towing at GCWR in extreme ambient conditions. During almost all other situations, this design characteristic may result in unnecessary energy usage for coolant pumping and heat rejection to the radiator.

The agencies considered whether to include electric oil pump technology for the rulemaking. Because it is necessary to operate the oil pump any time the engine is running, electric oil pump technology has insignificant effect on efficiency. Therefore, the agencies decided to not include electric oil pump technology.

(iii) Mild Hybrid

Mild hybrid systems offer idle-stop functionality and a limited level of regenerative braking and power assist. These systems replace the conventional alternator with a belt or crank driven starter/alternator and may add high voltage electrical accessories (which may include electric power steering and an auxiliary automatic transmission pump). The limited electrical requirements of these systems allow the use of lead-acid batteries or supercapacitors for energy storage, or the use of a small lithium-ion battery pack.

(iv) Strong Hybrid

A hybrid vehicle is a vehicle that combines two significant sources of propulsion energy, where one uses a consumable fuel (like gasoline), and one is rechargeable (during operation, or by another energy source). Hybrid technology is well established in the U.S. light-duty market and more manufacturers are adding hybrid models to their lineups. Hybrids reduce fuel consumption through three major mechanisms:

- The internal combustion engine can be optimized (through downsizing, modifying the operating cycle, or other control techniques) to operate at or near its most efficient point more of the time. Power loss from engine downsizing can be mitigated by employing power assist from the secondary power source.
- A significant amount of the energy normally lost as heat while braking can be captured and stored in the energy storage system for later use.
- The engine is turned off when it is not needed, such as when the vehicle is coasting or when stopped.

Hybrid vehicles utilize some combination of the three above mechanisms to reduce fuel consumption and CO₂ emissions. The effectiveness of fuel consumption and CO₂ reduction

depends on the utilization of the above mechanisms and how aggressively they are pursued. One area where this variation is particularly prevalent is in the choice of engine size and its effect on balancing fuel economy and performance. Some manufacturers choose not to downsize the engine when applying hybrid technologies. In these cases, overall performance (acceleration) is typically improved beyond the conventional engine. However, fuel efficiency improves less than if the engine was downsized to maintain the same performance as the conventional version. The non-downsizing approach is used for vehicles like trucks where towing and/or hauling are an integral part of their performance requirements. In these cases, if the engine is downsized, the battery can be quickly drained during a long hill climb with a heavy load, leaving only a downsized engine to carry the entire load. Because towing capability is currently a heavily-marketed truck attribute, manufacturers are hesitant to offer a truck with a downsized engine, which can lead to a significantly diminished towing performance when the battery state of charge level is low, and therefore engines are traditionally not downsized for these vehicles. In assessing the cost of this technology, the agencies consequently assumed the cost of a full size engine.

Strong Hybrid technology utilizes an axial electric motor connected to the transmission input shaft and connected to the engine crankshaft through a clutch. The axial motor is a motor/generator that can provide sufficient torque for launch assist, all electric operation, and the ability to recover significant levels of braking energy.

(e) Vehicle Technologies

(i) Mass Reduction

Mass reduction is a technology that can be used in a manufacturer's strategy to meet the Heavy Duty Greenhouse Gas Phase 2 standards. Vehicle mass reduction (also referred to as “down-weighting” or “light-weighting”), decreases fuel consumption and GHG emissions by reducing the energy demand needed to overcome inertia forces, and rolling resistance. Automotive companies have worked with mass reduction technologies for many years and a lot of these technologies have been used in production vehicles. The weight savings achieved by adopting mass reduction technologies offset weight gains due to increased vehicle size, larger powertrains, and increased feature content (sound insulation,

⁴⁸⁰ In the CAFE model, improved accessories refers solely to improved engine cooling.

entertainment systems, improved climate control, panoramic roof, etc.). Sometimes mass reduction has been used to increase vehicle towing and payload capabilities.

Manufacturers employ a systematic approach to mass reduction, where the net mass reduction is the addition of a direct component or system mass reduction, also referred to as primary mass reduction, plus the additional mass reduction taken from indirect ancillary systems and components, also referred to as secondary mass reduction or mass compounding. There are more secondary mass reductions achievable for light-duty vehicles compared to heavy-duty vehicles, which are limited due to the higher towing and payload requirements for these vehicles.

Mass reduction can be achieved through a number of approaches, even while maintaining other vehicle functionalities. As summarized by NAS in its 2011 light duty vehicle report,⁴⁸¹ there are two key strategies for primary mass reduction: (1) Changing the design to use less material; (2) substituting lighter materials for heavier materials.

The first key strategy of using less material compared to the baseline component can be achieved by optimizing the design and structure of vehicle components, systems and vehicle structure. Vehicle manufacturers have long used these continually-improving CAE tools to optimize vehicle designs. For example, the Future Steel Vehicle (FSV) project⁴⁸² sponsored by WorldAutoSteel used three levels of optimization: Topology optimization, low fidelity 3G (Geometry Grade and Gauge) optimization, and subsystem optimization, to achieve 30 percent mass reduction in the body structure of a vehicle with a mild steel unibody structure. Using less material can also be achieved through improving the manufacturing process, such as by using improved joining technologies and parts consolidation. This method is often used in combination with applying new materials.

The second key strategy to reduce mass of an assembly or component involves the substitution of lower density and/or higher strength materials. Material substitution includes replacing materials, such as mild steel,

with higher-strength and advanced steels, aluminum, magnesium, and composite materials. In practice, material substitution tends to be quite specific to the manufacturer and situation. Some materials work better than others for particular vehicle components, and a manufacturer may invest more heavily in adjusting to a particular type of advanced material, thus complicating its ability to consider others. The agencies recognize that like any type of mass reduction, material substitution has to be conducted not only with consideration to maintaining equivalent component strength, but also to maintaining all the other attributes of that component, system or vehicle, such as crashworthiness, durability, and noise, vibration and harshness (NVH).

If vehicle mass is reduced sufficiently through application of the two primary strategies of using less material and material substitution described above, secondary mass reduction options may become available. Secondary mass reduction is enabled when the load requirements of a component are reduced as a result of primary mass reduction. If the primary mass reduction reaches a sufficient level, a manufacturer may use a smaller, lighter, and potentially more efficient powertrain while maintaining vehicle acceleration performance. If a powertrain is downsized, a portion of the mass reduction may be attributed to the reduced torque requirement which results from the lower vehicle mass. The lower torque requirement enables a reduction in engine displacement, changes to transmission torque converter and gear ratios, and changes to final drive gear ratio. The reduced powertrain torque enables the downsizing and/or mass reduction of powertrain components and accompanying reduced rotating mass (e.g., for transmission, driveshafts/halfshafts, wheels, and tires) without sacrificing powertrain durability. Likewise, the combined mass reductions of the engine, drivetrain, and body in turn reduce stresses on the suspension components, steering components, wheels, tires, and brakes, which can allow further reductions in the mass of these subsystems. Reducing the unsprung masses such as the brakes, control arms, wheels, and tires further reduce stresses in the suspension mounting points, which will allow for further optimization and potential mass reduction. However, pickup trucks have towing and hauling requirements which must be taken into account when determining the amount of secondary

mass reduction that is possible and so it is less than that of passenger cars.

In 2015, EPA completed a multi-year study with FEV North America, Inc. on the lightweighting of a light-duty pickup truck, a 2011 GMC Silverado, titled "Mass Reduction and Cost Analysis—Light-Duty Pickup Trucks Model Years 2020–2025."⁴⁸³ Results contain a cost curve for various mass reduction percentages with the main solution being evaluated for a 20.8 percent (510 kg/1122 lb.) mass reduction resulting in an increased direct incremental manufacturing cost of \$2228. In addition, the report outlines the compounding effect that occurs in a vehicle with performance requirements including hauling and towing. Secondary mass evaluation was performed on a component level based on an overall 20 percent vehicle mass reduction. Results revealed 84 kg of the 510 kg, or 20 percent of the overall mass reduction, were from secondary mass reduction. Information on this study is summarized in SAE paper 2015-01-0559. NHTSA has also sponsored an on-going pickup truck lightweighting project. This project uses a more recent baseline vehicle, a MY 2014 GMC Silverado, and the project will be finished in 2016. Both projects will be utilized for the light-duty GHG and CAFE Midterm Evaluation mass reduction baseline characterization and may be used to update assumptions of mass reduction for HD pickups and vans for the final Phase 2 rulemaking.

In order to determine if technologies identified on light duty trucks are applicable to heavy-duty pickups, EPA contracted with FEV North America, Inc. to perform a scaling study in order to evaluate whether the technologies identified for the light-duty truck would be applicable for a heavy-duty pickup truck. In this study a 2013MY Silverado 2500, a 2007 Mercedes Sprinter and a 2010 Renault Master⁴⁸⁴ were analyzed. A 2013MY Silverado 2500 was purchased and torn down. The mass reduction results were 18.9 percent mass reduction at a cost of \$2,372 and focused on aluminum intensive with AHSS frame. The Mercedes Sprinter and Renault Master analyses were performed based on information from the A2Mac1 database. The results were 18.15 percent mass reduction at a cost add of \$2,293 for the Mercedes Sprinter

and 18.55 percent mass reduction at a cost add of \$2,293 for the Master.

In September 2015, Ford announced that its MY 2017 F-Series Super duty pickup (F250) would be manufactured with an aluminum body and overall the truck will be 350 lbs. lighter (5 percent–6 percent) than the current generation truck with steel.⁴⁸⁵ This is less overall mass reduction than the resultant lightweighting effort on the MY 2015 F–150, which achieved up to 750 lb. decrease in curb weight (12 percent–13 percent) per vehicle.⁴⁸⁷ Strategies were employed by Ford in the F250 to “improve the productivity of the Super Duty.” In addition, Ford added several safety systems (and consequent mass) including cameras, lane departure warning, brake assist, etc. More details on the F250 will be known once it is released; however, a review of the F150 vehicle aluminum intensive design shows that it has an aluminum cab structure, body panels, and suspension components, as well as a high strength steel frame and a smaller, lighter and more efficient engine. The Executive Summary to Ducker Worldwide’s 2014 report⁴⁸⁸ states that the MY 2015 F–150 contains 1080 lbs. of aluminum with at least half being aluminum sheet and extrusions for body and closures. Ford’s engine range for its light duty truck fleet includes a 2.7L EcoBoost V–6. The integrated loop, between Ford and the aluminum sheet suppliers, of aluminum manufacturing scrap and new aluminum sheet is integral to making aluminum a feasible lightweighting technology option for Ford. It is also possible that the strategy of aluminum body panels will be applied to the heavy duty F–350 version when it is redesigned.⁴⁸⁹

The RIA for this rulemaking shows that 10 percent or less mass reduction is part of the projected strategy for compliance for HD pickups and vans. The cost and effectiveness assumptions for mass reduction technology are described in the RIA.

(ii) Low Rolling Resistance Tires

Tire rolling resistance is the frictional loss associated mainly with the energy dissipated in the deformation of the tires under load and thus influences fuel efficiency and CO₂ emissions. Other tire design characteristics (e.g., materials, construction, and tread design) influence durability, traction (both wet and dry grip), vehicle handling, and ride comfort in addition to rolling resistance. A typical LRR tire’s attributes will include: Increased tire inflation pressure, material changes, and tire construction with less hysteresis, geometry changes (e.g., reduced aspect ratios), and reduction in sidewall and tread deflection. These changes will generally be accompanied with additional changes to suspension tuning and/or suspension design.

(iii) Aerodynamic Drag Reduction

Many factors affect a vehicle’s aerodynamic drag and the resulting power required to move it through the air. While these factors change with air density and the square and cube of vehicle speed, respectively, the overall drag effect is determined by the product of its frontal area and drag coefficient, Cd. Reductions in these quantities can therefore reduce fuel consumption and CO₂ emissions. Although frontal areas tend to be relatively similar within a vehicle class (mostly due to market-competitive size requirements), significant variations in drag coefficient can be observed. Significant changes to a vehicle’s aerodynamic performance may need to be implemented during a redesign (e.g., changes in vehicle shape). However, shorter-term aerodynamic reductions, with a somewhat lower effectiveness, may be achieved through the use of revised exterior components (typically at a model refresh in mid-cycle) and add-on devices that currently being applied. The latter list will include revised front and rear fascias, modified front air dams and rear valances, addition of rear deck lips and underbody panels, and lower aerodynamic drag exterior mirrors.

(f) Air Conditioning Technologies

These technologies include improved hoses, connectors and seats for leakage control. They also include improved compressors, expansion valves, heat exchangers and the control of these components for the purposes of improving tailpipe CO₂ emissions as a result of A/C use.⁴⁹⁰

⁴⁹⁰ See RIA Chapter 2.3 for more detailed technology descriptions.

(5) How did the agencies determine the costs and effectiveness of each of these technologies?

Building on the technical analysis underlying the 2017–2025 MY light-duty vehicle rule, the 2014–2018 MY heavy-duty vehicle rule, and the 2015 NHTSA Technology Study, the agencies took a fresh look at technology cost and effectiveness values for purposes of this rule. For costs, the agencies reconsidered both the direct (or “piece”) costs and indirect costs of individual components of technologies. For the direct costs, the agencies followed a bill of materials (BOM) approach employed by the agencies in the light-duty rule as well as referencing costs from the 2014–2018 MY heavy-duty vehicle rule and a new cost survey performed by Tetra Tech in 2014.

For two technologies, stoichiometric gasoline direct injection (SGDI) and turbocharging with engine downsizing, the agencies relied to the extent possible on the available tear-down data and scaling methodologies used in EPA’s ongoing study with FEV, Incorporated. This study consists of complete system tear-down to evaluate technologies down to the nuts and bolts to arrive at very detailed estimates of the costs associated with manufacturing them.⁴⁹¹

For the other technologies, considering all sources of information and using the BOM approach, the agencies worked together intensively to determine component costs for each of the technologies and build up the costs accordingly. Where estimates differ between sources, we have used engineering judgment to arrive at what we believe to be the best cost estimate available today, and explained the basis for that exercise of judgment.

Once costs were determined, they were adjusted to ensure that they were all expressed in 2012 dollars, and indirect costs were accounted for using a methodology consistent with the new ICM approach developed by EPA and used in the Phase 1 rule, and the 2012–2016 and 2017–2025 light-duty rules. NHTSA and EPA also reconsidered how costs should be adjusted by modifying or scaling content assumptions to account for differences across the range of vehicle sizes and functional requirements, and adjusted the associated material cost impacts to account for the revised content. We present the individual technology costs used in this analysis in Chapter 2.11 of the RIA.

⁴⁹¹ U.S. Environmental Protection Agency, “Draft Report—Light-Duty Technology Cost Analysis Pilot Study,” Contract No. EP–C–07–069, Work Assignment 1–3, September 3, 2009.

Regarding estimates for technology effectiveness, the agencies used the estimates from the 2014 Southwest Research Institute study as a baseline, which was designed specifically to inform this rulemaking. In addition, the agencies used 2017–2025 light-duty rule as a reference, and adjusted these estimates as appropriate, taking into account the unique requirement of the heavy-duty test cycles to test at curb weight plus half payload versus the light-duty requirement of curb plus 300 lbs. The adjustments were made on an individual technology basis by assessing the specific impact of the added load on each technology when compared to the use of the technology on a light-duty vehicle. The agencies also considered other sources such as the 2010 NAS Report, recent compliance data, and confidential manufacturer estimates of technology effectiveness. The agencies reviewed effectiveness information from the multiple sources for each technology and ensured that such effectiveness estimates were based on technology hardware consistent with the BOM components used to estimate costs. Together, the agencies compared the multiple estimates and assessed their validity, taking care to ensure that common BOM definitions and other vehicle attributes such as performance and drivability were taken into account.

The agencies note that the effectiveness values estimated for the technologies may represent average values applied to the baseline fleet described earlier, and do not reflect the potentially limitless spectrum of possible values that could result from adding the technology to different vehicles. For example, while the

agencies have estimated an effectiveness of 0.5 percent for low friction lubricants, each vehicle could have a unique effectiveness estimate depending on the baseline vehicle's oil viscosity rating. Similarly, the reduction in rolling resistance (and thus the improvement in fuel efficiency and the reduction in CO₂ emissions) due to the application of LRR tires depends not only on the unique characteristics of the tires originally on the vehicle, but on the unique characteristics of the tires being applied, characteristics which must be balanced between fuel efficiency, safety, and performance. Aerodynamic drag reduction is much the same—it can improve fuel efficiency and reduce CO₂ emissions, but it is also highly dependent on vehicle-specific functional objectives. For purposes of this final rule, the agencies believe that employing average values for technology effectiveness estimates is an appropriate way of recognizing the potential variation in the specific benefits that individual manufacturers (and individual vehicles) might obtain from adding a fuel-saving technology.

The assessment of the technology effectiveness and costs was determined from a combination of sources. First an assessment was performed by SwRI under contract with the agencies to determine the effectiveness and costs on several technologies that were generally not considered in the Phase 1 GHG rule time frame. Some of the technologies were common with the light-duty assessment but the effectiveness and costs of individual technologies were appropriately adjusted to match the expected effectiveness and costs when implemented in a heavy-duty

application. Finally, the agencies performed extensive outreach to suppliers of engine, transmission and vehicle technologies applicable to heavy-duty applications to get industry input on cost and effectiveness of potential GHG and fuel consumption reducing technologies. The agencies did not receive comments disputing the expected technology effectiveness values or costs developed with input from industry.

To achieve the levels of the Phase 2 standards for gasoline and diesel powered heavy-duty vehicles, a combination of the technologies previously discussed will be required respective to unique gasoline and diesel technologies and their challenges. Although some of the technologies may already be implemented in a portion of heavy-duty vehicles, none of the technologies discussed are considered ubiquitous in the heavy-duty fleet. Also, as will be expected, the available test data show that some vehicle models will not need the full complement of available technologies to achieve these standards. Furthermore, many technologies can be further improved (*e.g.*, aerodynamic improvements) from today's best levels, and so allow for compliance without needing to apply a technology that a manufacturer might deem less desirable.

Technology costs for HD pickups and vans are shown in Table VI–4. These costs reflect direct and indirect costs to the vehicle manufacturer for the 2021 model year. See Chapter 2.11. of the RIA for a more complete description of the basis of these costs.

TABLE VI–4—TECHNOLOGY COSTS FOR HD PICKUPS & VANS INCLUSIVE OF INDIRECT COST MARKUPS FOR MY 2021
[2012\$]

Technology	Gasoline	Diesel
Engine changes to accommodate low friction lubes	6	6
Engine friction reduction—level 1	116	116
Engine friction reduction—level 2	254	254
Dual cam phasing	183	183

^aCost to downsize from a V8 OHC to a V6 OHC engine with twin turbos.

As explained above, the CAFE model works by adding technologies in an incremental fashion to each particular vehicle in a manufacturer's fleet until that fleet complies with the imposed standards. It does this by following a predefined set of decision trees whereby the particular vehicle is placed on the appropriate decision tree and it follows the predefined progression of

technology available on that tree. At each step along the tree, a decision is made regarding the cost of a given technology relative to what already exists on the vehicle along with the fuel consumption improvement it provides relative to the fuel consumption at the current location on the tree, prior to deciding whether to take that next step on the tree or remain in the current

location. Because the model works in this way, the input files must be structured to provide costs and effectiveness values for each technology relative to whatever technologies have been added in earlier steps along the tree. Table VI-5 presents the cost and effectiveness values used in the CAFE model input files.

TABLE VI-5—CAFE MODEL INPUT VALUES FOR COST & EFFECTIVENESS FOR GIVEN TECHNOLOGIES ^a

Technology	FC savings (%)	Incremental cost (2012\$) ^{a b c}		
		2021	2025	2027
Improved Lubricants and Engine Friction Reduction	1.60	24	24	23

Notes:

^a Values for other model years available in CAFE model input files available at NHTSA Web site.

^b For mass reduction, cost reported on mass basis (per pound of curb weight reduction).

^c The model output has been adjusted to 2013\$.

^d 8-speed automatic transmission costs include costs for high efficiency gearbox and aggressive shift logic whereas those costs were kept separate in prior analyses.

In addition to the base technology cost and effectiveness inputs described above, the CAFE model accommodates inputs to adjust accumulated effectiveness under circumstances when combining multiple technologies could result in underestimation or overestimation of total incremental effectiveness relative to an “unevolved”

baseline vehicle. These so-called synergy factors may be positive, where the combination of the technologies results in greater improvement than the additive improvement of each technology, or negative, where the combination of the technologies is lower than the additive improvement of each technology. The synergy factors used in

the NPRM and Method B of the FRM are described in Table VI–6 Method A of the FRM uses synergies derived from a simulation project NHTSA undertook with Autonomie Argonne National Lab. A description of these changes is given in Section D.(8).

The CAFE model also accommodates inputs to adjust accumulated incremental costs under circumstances when the application sequence could result in underestimation or overestimation of total incremental costs relative to an “unevolved” baseline vehicle. For today’s analysis, the agencies have applied one such adjustment, increasing the cost of medium-sized gasoline engines by \$513 in cases where turbocharging and engine downsizing is applied with variable valve actuation.

The analysis performed using Method A also applied cost inputs to address some costs encompassed neither by the agencies’ estimates of the direct cost to apply these technologies, nor by the agencies’ methods for “marking up” these costs to arrive at increases in the new vehicle purchase costs. To account for the additional costs that could be incurred if a technology is applied and then quickly replaced, the CAFE model accommodates inputs specifying a “stranded capital cost” specific to each

technology. For this analysis, the model was run with inputs to apply about \$78 of additional cost (per engine) if gasoline engine turbocharging and downsizing (separately for each “level” considered) is applied and then immediately replaced, declining steadily to zero by the tenth model year following initial application of the technology. The model also accommodates inputs specifying any additional changes owners might incur in maintenance and post-warranty repair costs. For this analysis, the model was run with inputs indicating that vehicles equipped with less rolling-resistant tires could incur additional tire replacement costs equivalent to \$21–\$23 (depending on model year) in additional costs to purchase the new vehicle. The agencies did not, however, include inputs specifying any potential changes repair costs that might accompany application of any of the above technologies. A sensitivity analysis using Method A, discussed below, includes a case in which repair costs are

estimated using factors consistent with those underlying the indirect cost multipliers used to markup direct costs for the agencies’ central analysis.

(6) Regulatory Alternatives Considered by the Agencies

As discussed above, the model considers regulatory alternatives. The results of regulatory alternatives are considered relative to a “no action” alternative where existing standards persist, but no further regulatory action is taken (in this case the MY 2018 standards from Phase I are the last regulatory action taken). The agencies also considered four regulatory alternatives. The preferred alternative with a standard that increases 2.5 percent in stringency annually for MY’s 2021–2027, and three others with annual increases in stringency of: 2.0 percent, 3.5 percent, and 4.0 percent for MY’s 2021–2025. For each of the “action alternatives” (*i.e.*, those involving stringency increases beyond the no-action alternative), the annual

stringency increases are applied as follows: An annual stringency increase of r is applied by multiplying the model year 2020 target functions (identical to those applicable to model year 2018) by

$1 - r$ to define the model year 2021 target functions, multiplying the model year 2021 target functions by $1 - r$ to define the model year 2022 target functions, continuing through 2025 for

all alternatives except for the preferred Alternative 3 which extends through 2027. In summary, the agencies have considered the following five regulatory alternatives in the CAFE model.

TABLE VI-7—CONSIDERED REGULATORY ALTERNATIVES

Regulatory alternative	Annual stringency increase		
	2019–2020	2021–2025	2026–2027
1: No Action	None	None	None.
2: 2.0%/y	None	2.0%	None.
3: 2.5%/y	None	2.5%	2.5%.
4: 3.5%/y	None	3.5%	None.
5: 4.0%/y	None	4.0%	None.

(7) NPRM Modifications of the Model

The NPRM analysis (and the current analysis) reflect several changes made to the model since 2012, when NHTSA used the model to estimate the effects, costs, and benefits of final CAFE standards for light-duty vehicles produced during MYs 2017–2021, and augural standards for MYs 2022–2025. Some of these changes specifically enable analysis of potential fuel consumption standards (and, hence, CO₂ emissions standards harmonized with fuel consumption standards) for heavy-duty pickups and vans; other changes implement more general improvements to the model. Key changes include the following:

- Changes to accommodate standards for heavy-duty pickups and vans, including attribute-based standards involving targets that vary with “work factor.”
- Explicit calculation of test weight, taking into account test weight “bins” and differences in the definition of test weight for light-duty vehicles (curb weight plus 300 pound) and heavy-duty pickups and vans (average of GVWR and curb weight).
- Procedures to estimate increases in payload when curb weight is reduced, increases in towing capacity if GVWR is reduced, and calculation procedures to correspondingly update calculated work factors.
- Expansion of model inputs, procedures, and outputs to accommodate technologies not included in prior analyses.
- Changes to the algorithm used to apply technologies, enabling more explicit accounting for shared vehicle platforms and adoption and “inheritance” of major engine changes.

These changes are reflected in updated model documentation available at NHTSA’s Web site, the documentation also providing more information about the model’s purpose,

scope, structure, design, inputs, operation, and outputs. The agencies invited but did not receive comments on the CAFE model used for the NPRM analysis and used in this final rule for the Method B analysis.

(a) Product Cadence

Past comments on the CAFE model have stressed the importance of product cadence—*i.e.*, the development and periodic redesign and freshening of vehicles—in terms of involving technical, financial, and other practical constraints on applying new technologies, and NHTSA has steadily made changes to the model with a view toward accounting for these considerations. For example, early versions of the model added explicit “carrying forward” of applied technologies between model years, subsequent versions applied assumptions that most technologies would be applied when vehicles are freshened or redesigned, and more recent versions applied assumptions that manufacturers would sometimes apply technology earlier than “necessary” in order to facilitate compliance with standards in ensuing model years. Thus, for example, if a manufacturer is expected to redesign many of its products in model years 2018 and 2023, and the standard’s stringency increases significantly in model year 2021, the CAFE model will estimate the potential that the manufacturer will add more technology than necessary for compliance in MY 2018, in order to carry those product changes forward through the next redesign and contribute to compliance with the MY 2021 standard.

The model also accommodates estimates of overall limits (expressed as “phase-in caps” in model inputs) on the rates at which manufacturers’ may practicably add technology to their respective fleets. So, for example, even if a manufacturer is expected to redesign

half of its production in MY 2016, if the manufacturer is not already producing any strong hybrid electric vehicles (SHEVs), a phase-in cap can be specified in order to assume that manufacturer will stop applying SHEVs in MY 2016 once it has done so to at least 3 percent of its production in that model year.

After the light-duty rulemaking analysis accompanying the 2012 final rule regarding post-2016 CAFE standards and related GHG emissions standards, NHTSA staff began work on CAFE model changes expected to better reflect additional considerations involved with product planning and cadence. These changes, summarized below, interact with preexisting model characteristics discussed above.

(b) Platforms and Technology

The term “platform” is used loosely in industry, but generally refers to a common structure shared by a group of vehicle variants. The degree of commonality varies, with some platform variants exhibiting traditional “badge engineering” where two products are differentiated by little more than insignias, while other platforms be used to produce a broad suite of vehicles that bear little outer resemblance to one another.

Given the degree of commonality between variants of a single platform, manufacturers do not have complete freedom to apply technology to a vehicle: while some technologies (*e.g.* low rolling resistance tires) are very nearly “bolt-on” technologies, others involve substantial changes to the structure and design of the vehicle, and therefore necessarily are constant between vehicles that share a common platform. NHTSA staff has, therefore, modified the CAFE model such that all mass reduction and aero technologies are forced to be constant between variants of a platform. The agencies requested but did not receive comment on the suitability of this viewpoint, and

which technologies can deviate from one platform variant to another.

Within the analysis fleet, each vehicle is associated with a specific platform. As the CAFE model applies technology, it first defines a platform “leader” as the vehicle variant of a platform with the highest technology utilization vehicle of mass reduction and aerodynamic technologies. As the vehicle applies technologies, it effectively harmonizes to the highest common denominator of the platform. If there is a tie, the CAFE model begins applying aerodynamic and mass reduction technology to the vehicle with the lowest average sales across all available model years. If there remains a tie, the model begins by choosing the vehicle with the highest average MSRP across all available model years. The model follows this formulation due to previous market trends suggesting that many technologies begin deployment at the high-end, low-volume end of the market as manufacturers build their confidence and capability in a technology, and later expand the technology across more mainstream product lines.

In the HD pickup and van market, there is a relatively small amount of diversity in platforms produced by manufacturers: Typically 1–2 truck platforms and 1–2 van platforms. However, accounting for platforms will take on greater significance in future analyses involving the light-duty fleet. The agency requested but did not receive comments on the general use of platforms within CAFE rulemaking.

(c) Engine and Transmission Inheritance

In practice, manufacturers are limited in the number of engines and transmissions that they produce. Typically a manufacturer produces a number of engines—perhaps six or eight engines for a large manufacturer—and tunes them for slight variants in output for a variety of car and truck applications. Manufacturers limit complexity in their engine portfolio for much the same reason as they limit complexity in vehicle variants: They face engineering manpower limitations, and supplier, production and service costs that scale with the number of parts produced.

In previous usage of the CAFE model, engines and transmissions in individual models were allowed relative freedom in technology application, potentially leading to solutions that would, if followed, involve unaccounted-for costs associated with increased complexity in the product portfolio. The lack of a constraint in this area allowed the model to apply different levels of technology to the engine in each vehicle

at the time of redesign or refresh, independent of what was done to other vehicles using a previously identical engine.

In the current version of the CAFE model, engines and transmissions that are shared between vehicles must apply the same levels of technology in all technologies dictated by engine or transmission inheritance. This forced adoption is referred to as “engine inheritance” in the model documentation.

As with platform-shared technologies, the model first chooses an “engine leader” among vehicles sharing the same engine. The leader is selected first by the vehicle with the lowest average sales across all available model years. If there is a tie, the vehicle with the highest average MSRP across model years is chosen. The model applies the same logic with respect to the application of transmission changes. As with platforms, this is driven by the concept that vehicle manufacturers typically deploy new technologies in small numbers prior to deploying widely across their product lines.

(d) Interactions Between Regulatory Classes

Like earlier versions, the current CAFE model provides for integrated analysis spanning different regulatory classes, accounting both for standards that apply separately to different classes and for interactions between regulatory classes. Light vehicle CAFE standards are specified separately for passenger cars and light trucks. However, there is considerable sharing between these two regulatory classes. Some specific engines and transmissions are used in both passenger cars and light trucks, and some vehicle platforms span these regulatory classes. For example, some sport-utility vehicles are offered in 2WD versions classified as passenger cars and 4WD versions classified as light trucks. Integrated analysis of manufacturers’ passenger car and light truck fleets provides the ability to account for such sharing and reduce the likelihood of finding solutions that could involve impractical levels of complexity in manufacturers’ product lines. In addition, integrated analysis provides the ability to simulate the potential that manufacturers could earn CAFE credits by over complying with one standard and use those credits toward compliance with the other standard (*i.e.*, to simulate credit transfers between regulatory classes).

HD pickups and vans are regulated separately from light-duty vehicles. While manufacturers cannot transfer credits between light-duty and MDHD

classes, there is some sharing of engineering and technology between light-duty vehicles and HD pickups and vans. For example, some passenger vans with GVWR over 8,500 lbs. are classified as medium-duty passenger vehicles (MDPVs) and thus included in manufacturers’ light-duty truck fleets, while cargo vans sharing the same nameplate are classified as HD vans.

(e) Phase-In Caps

The CAFE model retains the ability to use phase-in caps (specified in model inputs) as proxies for a variety of practical restrictions on technology application. Unlike vehicle-specific restrictions related to redesign, refreshes or platforms/engines, phase-in caps constrain technology application at the vehicle manufacturer level. They are intended to reflect a manufacturer’s overall resource capacity available for implementing new technologies (such as engineering and development personnel and financial resources), thereby ensuring that resource capacity is accounted for in the modeling process.

In previous CAFE rulemakings, redesign/refresh schedules and phase-in caps were the primary mechanisms to reflect an OEM’s limited pool of available resources during the rulemaking time frame and the years leading up to the rulemaking time frame, especially in years where many models may be scheduled for refresh or redesign. The newly-introduced representation platform-, engine-, and transmission-related considerations discussed above augment the model’s preexisting representation of redesign cycles and accommodation of phase-in caps. Considering these new constraints, inputs for today’s analysis de-emphasize reliance on phase-in caps.

In the NPRM and Method B of the FRM application of the CAFE model, phase-in caps are used only for the most advanced technologies included in the analysis, *i.e.*, SHEVs and lean-burn GDI engines, considering that these technologies are most likely to involve implementation costs and risks not otherwise accounted for in corresponding input estimates of technology cost. For these two technologies, the agencies have applied caps that begin at 3 percent (*i.e.*, 3 percent of the manufacturer’s production) in MY 2017, increase at 3 percent annually during the ensuing nine years (reaching 30 percent in the MY 2026), and subsequently increasing at 5 percent annually for four years (reaching 50 percent in MY 2030). Note that the agencies did not feel that lean-burn engines were feasible in the

timeframe of this rulemaking, so decided to reject any model runs where they were selected. (In any case, due to the cost ineffectiveness of this technology, it was never chosen). The agencies did not receive comments specifically on this approach for phase-in caps. The agencies received comments regarding the general feasibility of SHEVs in this market segment, with some commenters commenting that SHEVs are not feasible for HD pickups and vans. These comments are discussed in Section C.8. While the agencies have retained the above approach for SHEV phase-in caps, the agencies have conducted a sensitivity analysis setting the SHEV caps at zero, showing that the Phase 2 standards are feasible and appropriate without the use of SHEVs. This sensitivity analysis is described in Section E.

For Method A of the NPRM the phase-in caps have been set to 100 percent, so that the model no longer relies on phase-in caps to limit the early-year application of advanced technologies. This change is further described in the Method B of the FRM specific section below.

(f) Impact of Vehicle Technology Application Requirements

Compared to prior analyses of light-duty standards, these model changes, along with characteristics of the HD

pickup and van fleet result in some changes in the broad characteristics of the model's application of technology to manufacturers' fleets. First, since the number of HD pickup and van platforms in a portfolio is typically small, compliance with standards may appear especially "lumpy" (compared to previous applications of the CAFE model to the more highly segmented light-duty fleet), with significant over compliance when widespread redesigns precede stringency increases, and/or significant application of carried-forward (aka "banked") credits.

Second, since the use of phase-in caps has been de-emphasized and manufacturer technology deployment remains tied strongly to estimated product redesign and freshening schedules, technology penetration rates may jump more quickly as manufacturers apply technology to high-volume products in their portfolio.

By design, restrictions that enforce commonality of mass reduction and aerodynamic technologies on variants of a platform, and those that enforce engine inheritance, will result in fewer vehicle-technology combinations in a manufacturer's future modeled fleet. These restrictions are expected to more accurately capture the true costs associated with producing and maintaining a product portfolio.

(g) Accounting for Test Weight, Payload, and Towing Capacity

As mentioned above, NHTSA has also revised the CAFE model to explicitly account for the regulatory "binning" of test weights used to certify light-duty fuel economy and HD pickup and van fuel consumption for purposes of evaluating fleet-level compliance with fuel economy and fuel consumption standards. For HD pickups and vans, test weight (TW) is based on adjusted loaded vehicle weight (ALVW), which is defined as the average of gross vehicle weight rating (GVWR) and curb weight (CW). TW values are then rounded, resulting in TW "bins":

ALVW ≤ 4,000 lb.: TW rounded to nearest 125 lb.

4000 lb. < ALVW ≤ 5,500 lb.: TW rounded to nearest 250 lb.

ALVW > 5,500 lb.: TW rounded to nearest 500 lb.

This "binning" of TW is relevant to calculation of fuel consumption reductions accompanying mass reduction. Model inputs for mass reduction (as an applied technology) are expressed in terms of a percentage reduction of curb weight and an accompanying estimate of the percentage reduction in fuel consumption, setting aside rounding of test weight. Therefore, to account for rounding of test weight, NHTSA has modified these calculations as follows:

$$\Delta FC_{\text{rounded\_TW}} = \Delta TW \times \frac{\Delta FC_{\text{unrounded\_TW}}}{\Delta CW}$$

Where:

ΔCW = % change in curb weight (from model input),

$\Delta FC_{\text{unrounded\_TW}}$ = % change in fuel consumption (from model input), without TW rounding,

ΔTW = % change in test weight (calculated), and

$\Delta FC_{\text{rounded\_TW}}$ = % change in fuel consumption (calculated), with TW rounding.

As a result, some applications of vehicle mass reduction will produce no compliance benefit at all, in cases where the changes in ALVW are too small to change test weight when rounding is taken into account. On the other hand, some other applications of vehicle mass reduction will produce significantly more compliance benefit than when rounding is not taken into account, in cases where even small changes in ALVW are sufficient to cause vehicles' test weights to increase by, e.g., 500 lbs.

when rounding is accounted for. Model outputs now include initial and final TW, GVWR, and GCWR (and, as before, CW) for each vehicle model in each model year. The agencies invited but did not receive comment on how TW is modeled.

In addition, considering that the regulatory alternatives in the agencies' analysis all involve attribute-based standards in which underlying fuel consumption targets vary with "work factor" (defined by the agencies as the sum of three quarters of payload, one quarter of towing capacity, and 500 lb. for vehicles with 4WD), NHTSA has modified the CAFE model to apply inputs defining shares of curb weight reduction to be "returned" to payload and shares of GVWR reduction to be returned to towing capacity. The standards' dependence on work factor provides some incentive to increase

payload and towing capacity, both of which are buyer-facing measures of vehicle utility. In the agencies' judgment, this provides reason to assume that if vehicle mass is reduced, manufacturers are likely to "return" some of the change to payload and/or towing capacity. For this analysis, the agencies have applied the following assumptions:

- GVWR will be reduced by half the amount by which curb weight is reduced. In other words, 50 percent of the curb weight reduction will be returned to payload.
- GCWR will not be reduced. In other words, 100 percent of any GVWR reduction will be returned to towing capacity.
- GVWR/CW and GCWR/GVWR will not increase beyond levels observed among the majority of similar vehicles (or, for outlier vehicles, initial values):

TABLE VI-8 RATIOS FOR MODIFYING GVW AND GCW AS A FUNCTION OF MASS REDUCTION

Group	Maximum ratios assumed enabled by mass reduction	
	GVWR/CW	GCWR/GVWR
Unibody	1.75	1.50
Gasoline pickups > 13k GVWR	2.00	1.50
Other gasoline pickups	1.75	2.25
Diesel SRW pickups	1.75	2.50
All other	1.75	2.25

The first of two of these inputs are specified along with standards for each regulatory alternative, and the GVWR/CW and GCWR/GVWR “caps” are specified separately for each vehicle model in the analysis fleet.

In addition, NHTSA has changed the model to prevent HD pickup and van GVWR from falling below 8,500 lbs. when mass reduction is applied (because doing so will cause vehicles to be reclassified as light-duty vehicles), and to treat any additional mass for hybrid electric vehicles as *reducing* payload by the same amount (*e.g.*, if adding a strong HEV package to a vehicle involves a 350 pound penalty, GVWR is assumed to remain unchanged, such that payload is also reduced by 350 lbs).

The agencies invited but did not receive comment on estimating how changes in vehicle mass may impact fuel consumption, GVWR, and GCWR.

(8) Subsequent Changes to the CAFE Model (for Method A)

Since issuing the NPRM, NHTSA has made further changes to the CAFE model, in order to estimate the potential impacts of simultaneous standards for both light-duty vehicles and HD pickups and vans. Among the updates most relevant to analysis supporting the final standards for HD pickups and vans, the current model: includes refinements to enable accounting for platforms, engines, and transmissions sharing between light-duty and HD pickups and vans; reflects refinements to how models for the first application of new technology are identified among shared platforms, engines, and transmissions; allows payback period, discount rate, survival rates, and mileage accumulation schedules to be specified separately for each vehicle class; makes use of large scale simulation modeling to more accurately account for synergies among technologies to estimate the fuel consumption impact of different combinations of technologies; provides the ability to selectively exclude fine payment from the “effective cost” calculation used to simulation manufacturers’ decisions regarding the

application of fuel-saving technologies; and expands the use of forward planning to estimate decisions to use credits that would otherwise expire. Changes to the CAFE model are discussed at greater length below and in the CAFE model documentation.

Also since issuing the NPRM, NHTSA has revised many model inputs to reflect information that has become available since the proposal. Among the updates most relevant to analysis supporting the final rule, these inputs reflect: an updated vehicle-level market forecast based on data regarding the 2015 model year fleet and a new commercially-available manufacturer- and segment-level market forecast, and spanning light-duty vehicles and HD pickups and vans; newer fuel prices and total vehicle production volumes from the Energy Information Administration’s Annual Energy Outlook 2015; a database, based on a large-scale full vehicle simulation study, of estimates of the effect of thousands of different combinations of technologies on fuel consumption; and updated mileage accumulation schedules based on a database of more than 70 million odometer readings.

NHTSA implemented these changes to the CAFE model and accompanying inputs to support both today’s final rule promulgating new fuel consumption standards for HD pickups and vans and the Draft Technical Assessment Report regarding agency’s consideration of CAFE standards for light duty vehicles for model years 2022–2025. This provided a basis to analyze the fleets simultaneously, accounting for interactions between the fleets; the draft RIA (p. 10–18) accompanying the NPRM identified this as a planned improvement for the final rule, and some stakeholders’ comments (*e.g.*, CARB,⁴⁹² UCS,⁴⁹³ and CBD⁴⁹⁴)

⁴⁹² CARB, Docket No. NHTSA–2014–0132–0125, at 17–18; 52–53.

⁴⁹³ UCS, Docket No. EPA–HQ–OAR–2014–0827–1329, at pages 23–24.

⁴⁹⁴ CBD, Docket No. NHTSA–2014–0132–0101 at pages 8–9.

indicated that such interactions should be accounted for.

The remainder of this section summarizes changes to the CAFE model and inputs made subsequent to the NPRM analysis, summarizes results of the updated analysis, and discusses.

(a) Interactions Between Regulatory Classes

Like earlier versions, the current CAFE model provides for integrated analysis spanning different regulatory classes, accounting both for standards that apply separately to different classes and for interactions between regulatory classes. Light vehicle CAFE standards are specified separately for passenger cars and light trucks. However, there is considerable sharing between these two regulatory classes. Some specific engines and transmissions are used in both passenger cars and light trucks, and some vehicle platforms span these regulatory classes. For example, some sport-utility vehicles are offered in 2WD versions classified as passenger cars and 4WD versions classified as light trucks. Integrated analysis of manufacturers’ passenger car and light truck fleets provides the ability to account for such sharing and reduce the likelihood of finding solutions that could involve impractical levels of complexity in manufacturers’ product lines. In addition, integrated analysis provides the ability to simulate the potential that manufacturers could earn CAFE credits by over complying with one standard and use those credits toward compliance with the other standard (*i.e.*, to simulate credit transfers between regulatory classes).

HD pickups and vans are regulated separately from light-duty vehicles. While manufacturers cannot transfer credits between light-duty and MDHD classes, there is some sharing of engineering and technology between light-duty vehicles and HD pickups and vans. For example, some passenger vans with GVWR over 8,500 pounds are classified as medium-duty passenger vehicles (MDPVs) and thus included in manufacturers’ light-duty truck fleets,

while cargo vans sharing the same nameplate are classified as HD vans.

The FRM Method A analysis uses an overall analysis fleet spanning both the light-duty and HD pickup and van fleets. As discussed below, doing so shows some technology “spilling over” to HD pickups and vans due, for example, to the application of technology in response to current light-duty standards. For most manufacturers, these interactions appear relatively small. For Nissan, however, they appear considerable, because Nissan’s heavy-duty vans use engines also used in Nissan’s light-duty SUVs. Unlike the Method A analysis, the Method B analysis is independent from the light-duty program.

In the NPRM proposing new standards for heavy-duty pickups and vans, NHTSA and EPA requested comment on the expansion of the analysis fleet such that the impacts of new HD pickup and van standards can be estimated within the context of an integrated analysis of light-duty vehicles and HD pickups and vans, accounting for interactions between the fleets. As mentioned above, some environmental organizations specifically cited commonalities and overlap between light- and heavy-duty products.

(b) Phase-In Caps

The model also accommodates estimates of overall limits (expressed as “phase-in caps” in model inputs) on the rates at which manufacturers’ may practicably add technology to their respective fleets. So, for example, even if a manufacturer is expected to redesign half of its production in MY 2016, if the manufacturer is not already producing any strong hybrid electric vehicles (SHEVs), a phase-in cap can be specified in order to assume that manufacturer will stop applying SHEVs in MY 2016 once it has done so to at least 3 percent of its production in that model year. Today’s analysis sets all of these caps at 100 percent, relying on other model constraints (in particular, the assumption that many technologies are

most practicably applied as part of a vehicle freshening or redesign) to estimate practicable technology application pathways.

The CAFE model retains the ability to use phase-in caps (specified in model inputs) as proxies for a variety of practical restrictions on technology application. Unlike vehicle-specific restrictions related to redesign, refreshes or platforms/engines, phase-in caps constrain technology application at the vehicle manufacturer level. Introduced in the 2006 version of the CAFE model, they were intended to reflect a manufacturer’s overall resource capacity available for implementing new technologies (such as engineering and development personnel and financial resources), thereby ensuring that resource capacity is accounted for in the modeling process.

In previous fuel efficiency rulemakings, redesign/refresh schedules and phase-in caps were the primary mechanisms to reflect an OEM’s limited pool of available resources during the rulemaking time frame and the years leading up to the rulemaking time frame, especially in years where many models may be scheduled for refresh or redesign. The newly-introduced representation platform-, engine-, and transmission-related considerations discussed above augment the model’s preexisting representation of redesign cycles, and as discussed above, inputs for today’s analysis de-emphasize reliance on phase-in caps.

(c) Accounting for Credits

The changes discussed above relate specifically to the model’s approach to simulating manufacturers’ potential addition of fuel-saving technology in response to fuel efficiency standards and fuel prices within an explicit product planning context. The model’s approach to simulating compliance decisions also accounts for the potential to earn and use fuel consumption credits, as provided by EPCA/EISA. Like past versions, the current CAFE model can be used to simulate credit carry-

forward (a.k.a. banking) between model years and transfers between the passenger car and light truck fleets, but not credit carry-back (a.k.a. borrowing) between model years or trading between manufacturers. Unlike past versions, the current CAFE model provides a basis to specify (in model inputs) fuel consumption credits available from model years earlier than those being simulated explicitly. For example, with today’s analysis representing model years 2015–2032 explicitly, credits specified as being available from model year 2014 are made available for use through model year 2019 (given the current 5-year limit on carry-forward of credits).

As discussed in the CAFE model documentation, the model’s default logic attempts to maximize credit carry-forward—that is to “hold on” to credits for as long as possible.⁴⁹⁵ Although the model uses credits before expiry if needed to cover shortfalls when insufficient opportunity to add technology is available to achieve compliance with a standard, the model will otherwise carry forward credits until they are about to expire, at which point it will use them before adding technology. As further discussed in the CAFE model documentation, model inputs can be used to adjust this logic to shift the use of credits ahead by one or more model years.

The example presented below illustrates how some of aspects of the current model logic around credits impacts estimation of technology application by a manufacturer within the context of a specified set of standards, focusing here on the model’s estimate of Ford’s potential technology application under the preferred alternative. Overall results for Ford and other manufacturers are summarized in Section VI.D.

⁴⁹⁵ Volpe CAFE Model Documentation, July 2016, pg 64. Available at <http://www.nhtsa.gov/Laws%20&%20Regulations/CAFE%20-%20Fuel%20Economy/cafe-volpe-model>.

Figure VI-5 Example of a Possible Compliance Strategy for Ford

Several aspects of the estimated achieved and required fuel consumption levels shown above are notable. First, the characteristics of Ford's fleet as represented in today's analysis fleet are such that the heavy duty pickup and van fleet falls short of average fuel efficiency standard in MY's 2023 through 2027. However, they exceed their standard for MY's 2016 through 2022. The current analysis uses logic that reflect the potential that Ford could use the 5-year carry forward provision to use fuel efficiency credits earned in MY's 2018 through MY 2022, to cover the shortfalls for MY's 2023 through 2027. The model assumes Ford will use as many of the MY 2018 expiring credits as necessary to cover the shortfall in MY 2023. For MY 2024 they will use all available MY 2019 credits before applying any additional MY 2020 credits necessary to cover the shortfall (in this particular case there are enough MY 2019 credits to cover the shortfall in MY 2024). This pattern continues for all model years where there is a shortfall—the model applies the oldest remaining credits first. Even so, today's analysis indicates Ford could be required to pay civil penalties for noncompliance without the addition of modest fuel savings in MY 2027. The change to the model which accounts for credits earned prior to MY 2015 is not illustrated in this example. However, Ford comes in with fuel consumption credits from MY's prior to MY 2015; if they had come in with an initial shortfall, they could have used these

banked credits to cover, at least a portion, of that shortfall.

As discussed above, these results provide an estimate, based on analysis inputs, of one way General Motors *could* add fuel-saving technologies to its products under the preferred alternative considered here, and are not a prediction of what General Motors *would* do under this alternative. In addition, it should be recognized that specific results vary among manufacturers and among regulatory alternatives (and under different analytical inputs). Still, the example should serve to illustrate how the ability to model credit banking can impact results.

(d) Integrating Vehicle Simulation Results Into the Synergy Values

The CAFE model does not itself evaluate which technologies will be available, nor does it evaluate how effective or reliable they will be. The technological availability and effectiveness rather, are predefined inputs to the model based on the agencies' judgements and not outputs from the model, which is simply a tool for calculating the effects of combining input assumptions.

In previous versions of the CAFE Model, technology effectiveness values entered into the model as a single number for each technology (for each of several classes), intended to represent the incremental improvement in fuel consumption achieved by applying that technology to a vehicle in a particular class. At a basic level, this implied that

successive application of new vehicle technologies resulted in an improvement in fuel consumption (as a percentage) that was the product of the individual incremental effectiveness of each technology applied. Since this construction fails to capture interactive effects—cases where a given technology either improves or degrades the impact of subsequently applied technologies—the CAFE Model applied “synergy factors.” The synergy factors were defined for a relatively small number of technology pairs, and were intended to represent the result of physical interactions among pairs of technologies—attempting to account for situations where $2 \times 2 \neq 4$.

For a more specific example, for a vehicle with an initial fuel consumption of FC_0 , if two technologies are applied, one with an incremental effectiveness of 5 percent, and a second with an incremental effectiveness of 10 percent, the effectiveness after the application of both technologies without consideration of synergies could be expressed as follows:

$$FC_0 * (1 - .05) * (1 - .1)$$

Which is equivalent to:

$$FC_0 * (1 - .145)$$

This suggests that the combined effectiveness of the two technologies is 14.5 percent. The synergy factors aim to correct for cases where fuel consumption improvements are not perfectly multiplicative, and the combined fuel consumption in the example above is either greater than or less than 14.5 percent.

For this analysis, the CAFE Model has been modified to accommodate the results of the large-scale vehicle simulation study conducted by Argonne National Laboratory (described in more detail in the light-duty Draft TAR). While Autonomie, Argonne's vehicle simulation model, produces absolute fuel consumption values for each simulation record, the results have been modified in a way that preserves much of the existing structure of the CAFE Model's compliance logic, but still faithfully reproduces the totality of the simulation outcomes present in the database. Fundamentally, the implementation represents a translation of the absolute values in the simulation database into incremental improvements and a substantially expanded set of synergy factors.

Since the simulation efforts only included light-duty vehicles, the effectiveness values for heavy duty were not integrated into the heavy-duty fleet; for future rule-makings NHTSA hopes to extend the vehicle simulation efforts to include simulations that would be relevant for heavy-duty pickups and vans. While the effectiveness values for individual technologies remain the same, the synergies between two or more technologies incorporate information from Autonomie Argonne's light-duty pickup simulations. While these synergy values are not a perfect approximation of the interaction of technology applications particular to heavy-duty vehicles, it is consistent with what we did in the NPRM (where we also used synergy values from light-duty pickups).

Updating the synergy values to use Argonne's simulation efforts does two things: (1) It allows that these synergies may occur between more than two technologies, and (2) because the synergies are multiplicative, rather than additive, it allows for the consideration that the order of other technology applications matter in determining the incremental percentage improvement correction of the synergy value. Instead of having one additive incremental percentage synergy value for a pair of technologies, regardless of the order of technology application between these pair of technologies, the synergy values are dependent on the initial state and ending point of a vehicle within the database.

As stated, in the past, synergy values in the Volpe model were represented as pairs. However, the new values are 7-tuples and there is one for every point in the database. The synergy factors are based (entirely) on values in the Argonne database, producing one for each unique technology combination for

each technology class, and are calculated as

$$S_k = \frac{FC_k}{FC_0 \cdot \prod(1 - x_i)}$$

where S_k is the synergy factor for technology combination k , FC_0 is the fuel consumption of the reference vehicle (in the database), x_i is the fuel consumption improvement of each technology i represented in technology combination k (where some technologies are present in combination k , and some are precedent technologies that were applied, incrementally, before reaching the current state on one of the paths).

In order to incorporate the results of the Argonne database, while still preserving the basic structure of the CAFE model's technology module, it was necessary to translate the points in the database into locations on the technology tree.⁴⁹⁶ By recognizing that most of the paths on the technology tree are unrelated, or separable, it is possible to decompose the technology tree into a small number of paths and branches by technology type. To achieve this level of linearity, we define technology groups—only one of which is new. They are: engine cam configuration (CONFIG), engine technologies (ENG), transmission technologies (TRANS), electrification (ELEC), mass reduction levels (MR), aerodynamic improvements (AERO), and rolling resistance (ROLL). The combination of technology levels along each of these paths define a unique technology combination that corresponds to a single point in the database for each technology class. These technology state definitions are more important for defining synergies than for determining incremental effectiveness, but the paths are incorporated into both. Again, because we did not simulate results applicable to the heavy-duty fleet, we did not use the database to define the incremental technology effectiveness, but only to adjust for the unique interaction of different combinations of technology.

As an example, a technology state vector describing a vehicle with a SOHC engine, variable valve timing (only), a 6-speed automatic transmission, a belt-integrated starter generator, mass reduction (level 1), aerodynamic improvements (level 2), and rolling resistance (level 1) would be specified as SOHC;VVT;AT6;BISG;MR1;AERO2;ROLL1. Once a vehicle is assigned a technology state (one of the tens of

thousands of unique 7-tuples, defined as CONFIG;ENG;TRANS;ELEC;MR;AERO;ROLL), adding a new technology to the vehicle simply represents progress from one technology state to another. The vehicle's fuel consumption is:

$$FC_i = FC_0 \cdot (1 - FCI_i) \cdot S_{K/0}$$

where FC_i is the fuel consumption resulting from the application of technology i , FC_0 is the vehicle's fuel consumption before technology i is applied, FCI_i is the incremental fuel consumption (percentage) improvement associated with technology i , S_k is the synergy factor associated with the combination, k , of technologies the vehicle technology i is applied, and S_0 the synergy factor associated with the technology state that produced fuel consumption FC_0 . The synergy factor is defined in a way that captures the incremental improvement of moving between points in the database, where each point is defined uniquely as a 7-tuple describing its cam configuration, highest engine technology, transmission, electrification type, mass reduction level, and level of aerodynamic or rolling resistance improvement. For the current heavy-duty adoption, it is only these synergy values that were used in the current analysis. While, like with the individual fuel consumption improvements, there is likely not a simple mapping from light-duty pickups to heavy-duty pickups (size and power matter), the previous synergy values were also an adoption from light-duty pickups. The integration of the simulation data allows for a more complete set of synergies that account for the order of technology application and the interaction of more than two individual technologies.

(e) Updating Mileage Accumulation Schedules

In order to develop new mileage accumulation schedules for vehicles regulated under NHTSA's fuel efficiency and CAFE programs (classes 1–3), NHTSA purchased a data set of vehicle odometer readings from IHS/Polk (Polk). Polk collects odometer readings from registered vehicles when they encounter maintenance facilities, state inspection programs, or interactions with dealerships and OEMs. The (average) odometer readings in the data set NHTSA purchased are based on over 74 million unique odometer readings across 16 model years (2000–2015) and vehicle classes present in the data purchase (all registered vehicles less than 14,000 lbs. GVW).

The Polk data provide a measure of the cumulative lifetime vehicle miles

⁴⁹⁶ The technology tree used to create the synergies for this rule are presented in the light-duty draft TAR.

traveled (VMT) for vehicles, at the time of measurement, aggregated by the following parameters: make, model, model year, fuel type, drive type, door count, and ownership type (commercial or personal). Within each of these subcategories they provide the average odometer reading, the number of odometer readings in the sample from which Polk calculated the averages, and the total number of that subcategory of vehicles in operation. From these NHTSA was able to develop new estimates of vehicle miles traveled by age as inputs for the CAFE Model.

(f) Impact of Vehicle Technology Application Requirements

Compared to prior analyses of light-duty standards, these model changes result in some changes in the broad characteristics of the model's application of technology to manufacturers' fleets. Since the use of phase-in caps has been de-emphasized

and manufacturer technology deployment remains tied strongly to estimated product redesign and freshening schedules, technology penetration rates may jump more quickly as manufacturers apply technology to high-volume products in their portfolio.

By design, restrictions that enforce commonality of mass reduction and aerodynamic technologies on variants of a platform, and those that enforce engine inheritance, will result in fewer vehicle-technology combinations in a manufacturer's future modeled fleet. As explained in the NPRM proposing new standards for HD pickups and vans, these restrictions are expected to more accurately capture the true costs associated with producing and maintaining a product portfolio.

(i) Updated Schedules

The new medium-duty van/pickup schedule in Figure VI-6 predicts higher

annual VMT for vehicles between ages one through five years, and lower annual VMT for all other vehicle ages, than the old schedule. Over the first 30-year span, the new schedule predicts that medium-duty vans/pickups drive 24,249 (9 percent) fewer miles than the old schedule. We predict the maximum average annual VMT for medium-duty vehicles (23,307 miles) at age two. These changes to the schedule will have important implications on certain benefits of the standards. More monetary fuel savings will occur during the first five years of a vehicle's life under the new schedule, but a decrease in fuel savings will occur overall while using these schedules. For payback periods shorter than 5 years, the new schedule will show shorter payback periods than the old schedule. Section 10 of the RIA offers similar figures for light-duty vehicles types. It also offers further explanation about the shape of the new annual VMT schedule.

Figure VI-6 A Comparison of the New and Old Heavy-Duty Van/Pickup Schedules

Table VI-9 offers a summary of the comparison of lifetime VMT (by class) under the new schedule, compared with lifetime VMT under the old schedule. In addition to the total lifetime VMT expected under each schedule for vehicles that survive to their full useful

life, Table VI-9 also shows the survival-weighted lifetime VMT for both schedules. This represents the average lifetime VMT for all vehicles, not only those that survive to their full useful life. The percentage difference between the two schedules is not as stark for the

survival-weighted schedules: The percentage decrease of survival-weighted lifetime VMT under the new schedules range from 6.5 percent (for medium-duty trucks and vans) to 21.2 percent (for passenger vans).

TABLE VI-9—SUMMARY COMPARISON OF LIFETIME VMT OF THE NEW AND OLD SCHEDULES

	Lifetime VMT			Survival-Weighted		
				Lifetime VMT		
	New	Old	% difference	New	Old	% difference
Car	204,233	301,115	32.2	142,119	179,399	20.8
Van	237,623	362,482	34.4	155,115	196,725	21.2
SUV	237,623	338,646	29.8	155,115	193,115	19.7
Pickup	265,849	360,982	26.4	157,991	188,634	16.2
2b/3	246,413	270,662	9.0	176,807	189,020	6.5

(ii) Data Description

While the Polk data set contains model-level average odometer readings, the CAFE model assigns lifetime VMT schedules at a lower resolution based on vehicle body style. For the purposes of VMT accounting, the CAFE model classifies every vehicle in the analysis fleet as being one of the following: passenger car, SUV, pickup truck, passenger van, or medium-duty pickup/van. In order to use the Polk data to develop VMT schedules for each of the (VMT) classes in the CAFE model, we constructed a mapping between the classification of each model in the Polk data and the classes in the CAFE model. The only difference between the mapping for the VMT schedules and the rest of the CAFE model is that we merged the SUV and van body styles into one class (for reasons described in our discussion of the SUV/van schedule in Section 10 of the RIA). This mapping allowed us to predict the lifetime miles traveled, by the age of a vehicle, for the categories in the CAFE model.

In estimating the VMT models, we weighted each data point (make/model classification) by the share of each make/model in the total population of the corresponding CAFE class. This weighting ensures that the predicted odometer readings, by class and model year, represent each of vehicle classification among observed vehicles (*i.e.*, the vehicles for which Polk has odometer readings), based on each vehicles' representation in the registered vehicle population of its class. Implicit in this weighting scheme, is the assumption that the samples used to calculate each average odometer reading by make, model, and model year are representative of the total population of vehicles of that type. Several indicators suggest that this is a reasonable assumption.

First, the majority of each vehicle make/model is well-represented in the sample. For more than 85 percent of make/model combinations, the average odometer readings are collected for 20 percent or more of the total population.

Most make/model observations have sufficient sample sizes, relative to their representation in the vehicle population, to produce meaningful average odometer totals at that level.

We also considered whether the representativeness of the odometer sample varies by vehicle age, since VMT schedules in the CAFE model are specific to each age. To investigate, we calculated the percentage of vehicle types (by make, model, and model year) that did not have odometer readings. All model years, apart from 2015, have odometer readings for 96 percent or more of the total types of vehicles observed in the fleet.

While the preceding discussion supports the *coverage* of the odometer sample across makes/models by each model year, it is possible that, for some of those models, an insufficient number of odometer readings is recorded to create an average that is likely to be representative of all of those models in operation for a given year. For all model years other than 2015, about 95 percent or more of vehicles types are represented by at least 5 percent of their population. For this reason, we included observations from all model years, other than 2015, in the estimation of the new VMT schedules.

It is possible that the odometer sample is biased. If certain vehicles are over-represented in the sample of odometer readings relative to the registered vehicle population, a simple average, or even one weighted by the number of odometer observations will be biased. However, while weighting by the share of each vehicle in the population will account for this bias, it would not correct for a sample that entirely omits a large number of makes/models within a model year. We tested for this by computing the proportion of the count of odometer readings for each individual vehicle type—within a class and model year—to the total count of readings for that class and model year. We also compared the population of each make/model—within each class and model year—to the population of the corresponding class and model year.

The difference of these two ratios shows the difference of the representation of a vehicle type—in its respective class and model year—in the sample versus the population. All vehicle types are represented in the sample within 10 percent of their representation in the population, and the variance between the two representations is normally distributed. This suggests that, on average, the likelihood that a vehicle is in the sample is comparable to its proportion in the relevant population, and that there is little under or over sampling of certain vehicle makes/models.⁴⁹⁷

(iii) Estimation

Since model years are sold in in the fall of the previous calendar year, throughout the same calendar year, and even into the following calendar year—not all registered vehicles of a make/model/model year will have been registered for at least a year (or more) until age 3. The result is that some MY 2014 vehicles may have been driven for longer than one year, and some less, at the time the odometer was observed. In order to consider this in our definition of age, we assign the age of a vehicle to be the difference between the average reading date of a make/model and the average first registration date of that make/model. The result is that the continuous age variable reflects the amount of time that a car has been registered at the time of odometer reading, and presumably the time span that the car has accumulated the miles.

After creating the “Age” variable, we fit the make/model lifetime VMT data points to a weighted quartic polynomial regression of the age of the vehicle (stratified by class). The predicted values of the quartic regressions are used to calculate the marginal annual VMT by age for each class by calculating differences in estimated lifetime mileage accumulation by age. However, the Polk data acquired by NHTSA only contains

⁴⁹⁷ For figures that support the conclusions about the representativeness of the IHS/Polk data see Section 10 of the RIA.

observations for vehicles newer than 16 years of age. In order to estimate the schedule for vehicles older than the age 15 vehicles in the Polk data, we combined information about that portion of the schedule from the VMT schedules used in both the 2017–2021 Final Light Duty Rule and 2019–2025 Medium-Duty NPRM. The light-duty schedules were derived from the survey data contained in the 2009 National Household Travel Survey (NHTS) and the 2001 Vehicle in Use Survey (VIUS), for medium-duty trucks.

Based on the vehicle ages for which we have data (from the Polk purchase), the newly estimated annual schedules differ from the previous version in important ways. Perhaps most significantly, the annual mileage associated with ages beyond age 8 begin to, and continue to, trend much lower. The approach taken here attempts to preserve the results obtained through estimation on the Polk observations, while leveraging the existing (NHTS-based) schedules to support estimation of the higher ages (age 16 and beyond). Since the two schedules are so far apart, simply splicing them together would have created not only a discontinuity, but also precluded the possibility of a monotonically decreasing scale with age (which is consistent with previous schedules, the data acquired from Polk, and common sense).

From the old schedules, we expect that the annual VMT is decreasing for all ages. Towards the end of our sample, the predictions for annual VMT increase. In order to force the expected monotonicity, we perform a triangular smoothing algorithm until the schedule is monotonic. This performs a weighted average which weights the observations close to the observation more than those farther from it. The result is a monotonic function, which predicts similar lifetime VMT for the sample span as the original function. Since we do not have data beyond 15 years of age,

we are not able to correctly capture that part of the annual VMT curve using only the new dataset. For this reason, we use trends in the old data to extrapolate the new schedule for ages beyond the sample range.

In order to use the VMT information from the newer data source for ages outside of the sample, we use the final in-sample age (15 years) as a seed and then apply the proportional trend from the old schedules to extrapolate the new schedules out to age 30. To do this, we calculated the annual percentage difference in VMT of the old schedule for ages 15–30. The same annual percentage difference in VMT is applied to the new schedule to extend beyond the final in-sample value. This assumes that the overall proportional trend in the outer years is correctly modeled in the old VMT schedule, and imposes this same trend for the outer years of the new schedule. The extrapolated schedules are the final input for the VMT schedules in the CAFE model.

(iv) Comparison to Previous Schedules

The new VMT data suggests that the VMT schedule used in the last Light-Duty CAFE Final Rule likely does not represent current annual VMT rates. Across all classes, the previous VMT schedules overestimate the average annual VMT. The previous schedules are based on data that is outdated and self-reported, while the observations from Polk are between 5 and 7 years newer than those in the NHTS and represent valid odometer readings (rather than self-reported information).

Additionally, while the NHTS may be a representative sample of *households*, it is less likely to be a representative sample of *vehicles*. However, by properly accounting for vehicle population weights in the new averages and models, we corrected for this issue in the derivation of the new schedules.

Insofar as these changes better represent actual VMT, they lead to

better estimates of actual impacts, such as avoided fuel consumption and GHG emissions, safety impacts, and monetized benefits.

(v) Future Direction

In consultation with other agencies closely involved with VMT estimation (e.g., FHWA), NHTSA will continue to seek means to further refine estimated mileage accumulation schedules. For example, one option under consideration would be to obtain odometer reading data from successive calendar years, thus providing a more robust basis to consider, for example, the influence of changing fuel prices or economic conditions on the accumulation of miles by vehicles of a given age.

(g) Updated Analysis Fleet

For the current analysis we updated the reference fleet from MY 2014, to the latest available MY 2015. The projection of total sales volumes for the Class 2b and 3 market segment was based on the total volumes in the 2015 AEO Reference Case. For the purposes of this analysis, the AEO2015 calendar year volumes have been used to represent the corresponding model-year volumes. While AEO2015 provides enough resolution in its projections to separate the volumes for the Class 2b and 3 segments, the agencies deferred to the vehicle manufacturers and chose to rely on the relative shares present in the pre-model-year compliance data.

The relative sales share by vehicle type (van or pickup truck, in this case) was derived from a sales forecast that the agencies purchased from IHS Automotive, and applied to the total volumes in the AEO2015 projection. Table VI–10 shows the implied shares of the total new 2b/3 vehicle market broken down by manufacturer and vehicle type.

TABLE VI–10—2015 IHS AUTOMOTIVE MARKET SHARE FORECAST FOR 2B/3 VEHICLES

Manufacturer	Style	Model year market share					
		2016	2017	2018	2019	2020	2021
Daimler	Van	2%	2%	2%	3%	3%	3%
Fiat Chrysler	Van	3	3	3	3	3	3
Ford	Van	16	16	16	17	18	19
General Motors	Van	7	7	7	7	8	8
Nissan	Van	1	1	1	1	2	2
Daimler	Pickup	0	0	0	0	0	0
Fiat Chrysler	Pickup	14	14	14	14	15	14
Ford	Pickup	29	30	31	31	28	28
General Motors	Pickup	28	27	26	25	24	24
Nissan	Pickup	0	0	0	0	0	0

Within those broadly defined market shares, volumes at the manufacturer/model-variant level were constructed by applying the model-variant's share of manufacturer sales in the pre-model-year compliance data for the relevant vehicle style, and multiplied by the total volume estimated for that manufacturer and that style.

(h) Changes to Costs

(i) Use of Retail Price Equivalent (RPE) Multiplier To Calculate Indirect Costs

To produce a unit of output, vehicle manufacturers incur direct and indirect costs. Direct costs include cost of materials and labor costs. Indirect costs are all the costs associated with producing the unit of output that are not direct costs—for example, they may be related to production (such as research and development [R&D]), corporate operations (such as salaries, pensions, and health care costs for corporate staff),

or selling (such as transportation, dealer support, and marketing). Indirect costs are generally recovered by allocating a share of the costs to each unit of good sold. Although it is possible to account for direct costs allocated to each unit of good sold, it is more challenging to account for indirect costs allocated to a unit of goods sold. To make a cost analysis process more feasible, markup factors, which relate total indirect costs to total direct costs, have been developed. These factors are often referred to as retail price equivalent (RPE) multipliers.

Cost analysts and regulatory agencies (including both NHTSA and EPA) have frequently used these multipliers to predict the resultant impact on costs associated with manufacturers' responses to regulatory requirements. The best approach, if it were possible, to determining the impact of changes in direct manufacturing costs on a

manufacturer's indirect costs would be to actually estimate the cost impact on each indirect cost element. However, doing this within the constraints of an agency's time or budget is not always feasible, and the technical, financial, and accounting information to carry out such an analysis may simply be unavailable.

The one empirically derived metric that addresses the markup of direct costs to consumer costs is the RPE multiplier, which is measured from manufacturer 10-K accounting statements filed with the Securities and Exchange Commission. Over roughly a three decade period, the measured RPE has been remarkably stable, averaging 1.5, with minor annual variation. The National Research Council notes that, "Based on available data, a reasonable RPE multiplier would be 1.5." The historical trend in the RPE is illustrated in Figure VI.13.

Figure VI-7 RPE History 1972-1997 and 2007

RPE multipliers provide, at an aggregate level, the relationship between revenue and direct manufacturing costs. They are measured by dividing total revenue by direct costs. However, because this provides only a single aggregate measure, using RPE multipliers results in the application of a common incremental markup to all technologies. It assures that the aggregate cost impact across all technologies is consistent with empirical data, but does not allow for indirect cost discrimination among different technologies. Thus, a concern

in using the RPE multiplier in cost analysis for new technologies added in response to regulatory requirements is that the indirect costs of vehicle modifications are not likely to be the same for all different technologies. For example, less complex technologies could require fewer R&D efforts or less warranty coverage than more complex technologies. In addition, some simple technological adjustments may, for example, have no effect on the number of corporate personnel and the indirect costs attributable to those personnel. The use of RPEs, with their assumption

that all technologies have the same proportion of indirect costs, is likely to overestimate the costs of less complex technologies and underestimate the costs of more complex technologies. However, for regulations such as the CAFE and GHG emission standards under consideration, which drive changes to nearly every vehicle system, overall average indirect costs should align with the RPE value. Applying RPE to the cost for each technology assures that alignment.

Modified multipliers have been developed by EPA, working with a

contractor, for use in rulemakings.⁴⁹⁸ These multipliers are referred to as indirect cost multipliers (or ICMs). ICMs assign unique incremental changes to each indirect cost contributor at several different technology levels.

ICM = (direct cost + adjusted indirect cost)/(direct cost)

Developing the ICMs from the RPE multipliers requires developing adjustment factors based on the complexity of the technology and the time frame under consideration: The less complex a technology, the lower its ICM, and the longer the time frame for applying the technology, the lower the ICM. This methodology was used in the cost estimation for the recent light-duty MYs 2012–2016 and MYs 2017–2025 rulemaking and for the heavy-duty MYs 2014–2018 rulemaking. The ICMs for the light-duty context were developed in a peer-reviewed report from RTI International and were subsequently discussed in a peer-reviewed journal article.⁴⁹⁹ Importantly, since publication of that peer-reviewed journal article, the agencies have revised the methodology to include a return on capital (*i.e.*, profits) based on the assumption implicit in ICMs (and RPEs) that capital costs are proportional to direct costs, and businesses need to be able to earn returns on their investments.

Since their original development in February 2009, the agencies have made some changes to both the ICMs factors and to the method of applying those factors relative to the factors developed by RTI and presented in their reports. We have described and explained those changes in several rulemakings over the years, most notably the 2017–2025 FRM for light vehicles and the more recent Heavy-duty GHG Phase 2 NPRM.⁵⁰⁰ In the 2015 NAS study, the committee stated a conceptual agreement with the ICM method since ICM takes into account design challenges and the activities required to implement each technology. However, although endorsing ICMs as a concept, the NAS Committee stated that “. . . the empirical basis for such multipliers is still lacking, and, since their application depends on expert judgment, it is not possible to determine whether the Agencies’ ICMs are accurate or not.” NAS also states that “. . . the specific

values for the ICMs are critical since they may affect the overall estimates of costs and benefits for the overall standards and the cost effectiveness of the individual technologies.” The committee did encourage continued research into ICMs given the lack of empirical data for them to evaluate the ICMs used by the agencies in past analyses. EPA, for its part, continues to study the issue surrounding ICMs but has not pursued further efforts given resource constraints and demands in areas such as technology benchmarking and cost teardowns.

On balance, NHTSA believes that the empirically derived RPE is a more reliable basis for estimating indirect costs. To ensure overall indirect costs in the analysis align with the RPE value, NHTSA has developed its primary analysis based on applying the RPE value of 1.5 to each technology. NHTSA also has conducted a sensitivity analysis examining the impact of applying the ICM approach in the sensitivity analysis portion later in this Section. This marks a change from the NPRM where we use the ICM multiplier to calculate indirect costs as the central analysis and the RPE multiplier as a sensitivity case.

(ii) Updates to Mass Reduction Based on 2014 Silverado Study

As proposed in the NPRM we have updated the HD pickup and van mass reduction cost curves with a MY 2014 GMC Silverado EDAG study. The updated mass reduction study suggests that mass reduction will be more costly for heavy-duty vans and pickups than was suggested in the NPRM. This can explain the reduction in mass reduction in the current analysis compared to the NPRM.

NHTSA awarded a contract to EDAG to conduct a vehicle weight reduction feasibility and cost study of a 2014MY full size pick-up truck. The light weighted version of the full size pick-up truck (LWT) used manufacturing processes that will likely be available during the model years 2025–2030 and be capable of high volume production. The goal was to determine the maximum feasible weight reduction while maintaining the same vehicle functionalities, such as towing, hauling, performance, noise, vibration, harshness, safety, and crash rating, as the baseline vehicle, as well as the functionality and capability of designs to meet the needs of sharing components across same or cross vehicle platform. Consideration was also given to the sharing of engines and other components with vehicles built on other platforms to achieve manufacturing economies of scale, and

in recognition of resource constraints which limit the ability to optimize every component for every vehicle.

A comprehensive teardown/benchmarking of the baseline vehicle was conducted for the engineering analysis. The analysis included geometric optimization of load bearing vehicle structures, advanced material utilization along with a manufacturing technology assessment that would be available in the 2017 to 2025 time frame. The baseline vehicle’s overall mass, center of gravity and all key dimensions were determined. Before the vehicle teardown, laboratory torsional stiffness tests, bending stiffness tests and normal modes of vibration tests were performed on baseline vehicles so that these results could be compared with the CAE model of the light weighted design. After conducting a full tear down and benchmarking of the baseline vehicle, a detailed CAE model of the baseline vehicle was created and correlated with the available crash test results. The project team then used computer modeling and optimization techniques to design the light-weighted pickup truck and optimized the vehicle structure considering redesign of structural geometry, material grade and material gauge to achieve the maximum amount of mass reduction while achieving comparable vehicle performance as the baseline vehicle. Only technologies and materials projected to be available for large scale production and available within two to three design generations (*e.g.* model years 2020, 2025 and 2030) were chosen for the LWT design. Three design concepts were evaluated: (1) A multi-material approach; (2) an aluminum intensive approach; and (3) a Carbon Fiber Reinforced Plastics approach. The multi-material approach was identified as the most cost effective. The recommended materials (advanced high strength steels, aluminum, magnesium and plastics), manufacturing processes, (stamping, hot stamping, die casting, extrusions, and roll forming) and assembly methods (spot welding, laser welding, riveting and adhesive bonding) are currently used, although some to a lesser degree than others. These technologies can be fully developed within the normal product design cycle using the current design and development methods.

The design of the LWT was verified, through CAE modeling, that it meets all relevant crash tests performance. The LS-DYNA finite element software used by the EDAG team is an industry standard for crash simulation and modeling. The researchers modeled the crashworthiness of the LWT design

⁴⁹⁹ Rogozhin, A., et al., “Using indirect cost multipliers to estimate the total cost of adding new technology in the automobile industry,” International Journal of Production Economics (2009), doi:10.1016/j.ijpe.2009.11.031.

⁵⁰⁰ 80 FR 40137.

using the NCAP Frontal, Lateral Moving Deformable Barrier, and Lateral Pole tests, along with the IIHS Roof, Lateral Moving Deformable Barrier, and Frontal Offset (40 percent and 25 percent) tests. All of the modeled tests were comparable to the actual crash tests performed on the 2014 Silverado in the NHTSA database. Furthermore, the FMVSS No. 301 rear impact test was modeled and it showed no damage to the fuel system.

The baseline 2014 MY Chevrolet Silverado's platform shares components across several platforms. Some of the chassis components and other structural components were designed to accommodate platform derivatives, similar to the components in the baseline vehicle which are shared across platforms such as GMT 920 (GM Tahoe, Cadillac Escalade, GMC Yukon), GMT 930 platform (Chevy Suburban, Cadillac Escalade ESV, GMC Yukon XL), and GMT 940 platform (Chevy Avalanche and Cadillac Escalade EXT) and GMT 900 platform (GMC Sierra). As per the National Academy of Science's guidelines, the study assumes engines would be downsized or redesigned for mass reduction levels at or greater than 10 percent. As a consequence of mass reduction, several of the components used designs that were developed for other vehicles in the weight category of light-weighted designed vehicles were used to maximize economies of scale and resource limitations. Examples

include brake systems, fuel tanks, fuel lines, exhaust systems, wheels, and other components.

Cost is a key consideration when vehicle manufacturers decide which fuel-saving technology to apply to a vehicle. Incremental cost analysis for all of the new technologies applied to reduce mass of the light-duty full-size pickup truck designed were calculated. The cost estimates include variable costs as well as non-variable costs, such as the manufacturer's investment cost for tooling. The cost estimates include all the costs directly related to manufacturing the components. For example, for a stamped sheet metal part, the cost models estimate the costs for each of the operations involved in the manufacturing process, starting from blanking the steel from coil through the final stamping operation to fabricate the component. The final estimated total manufacturing cost and assembly cost are a sum total of all the respective cost elements including the costs for material, tooling, equipment, direct labor, energy, building and maintenance.

The information from the LWT design study was used to develop a cost curve representing cost effective full vehicle solutions for a wide range of mass reduction levels. At lower levels of mass reduction, non-structural components and aluminum closures provide weight reduction which can be incorporated independently without the redesign of

other components and are stand-alone solutions for the LWV. The holistic vehicle design using a combination of AHSS and aluminum provides good levels of mass reduction at reasonably acceptable cost. The LWV solution achieves 17.6 percent mass reduction from the baseline curb mass. Further two more analytical mass reduction solutions (all aluminum and all carbon fiber reinforced plastics (CFRP)) were developed to show additional mass reduction that could be potentially achieved beyond the LWV mass reduction solution point. The aluminum analytical solution predominantly uses aluminum including chassis frame and other components. The carbon fiber reinforced plastics analytical solution predominantly uses CFRP in many of the components. The CFRP analytical solution shows higher level of mass reduction but at very high costs. Note here that both all-Aluminum and all CFRP mass reduction solutions are analytical solutions only and no computational models were developed to examine all the performance metrics.

An analysis was also conducted to examine the cost sensitivity of major vehicle systems to material cost and production volume variations.

Table VI–11 lists the components included in the various levels of mass reduction for the LWV solution. The components are incorporated in a progression based on cost effectiveness.

TABLE VI–11—COMPONENTS INCLUDED FOR DIFFERENT LEVELS OF MASS REDUCTION

Vehicle component/system	Cumulative mass saving (kg)	Cumulative MR (%)	Cumulative cost (\$)	Cumulative cost (\$/kg)
Interior Electrical Wiring	1.38	0.06%	(28.07)	– 20.34
Headliner	1.56	0.06	(29.00)	– 18.59
Trim—Plastic	2.59	0.11	(34.30)	– 13.24
Trim—misc.	4.32	0.18	(43.19)	– 10.00
Floor Covering	4.81	0.20	(45.69)	– 9.50
Headlamps	6.35	0.26	(45.69)	– 7.20
HVAC System	8.06	0.33	(45.69)	– 5.67
Tail Lamps	8.46	0.35	(45.69)	– 5.40
Chassis Frame	54.82	2.25	2.57	0.05
Front Bumper	59.93	2.46	7.89	0.13
Rear Bumper	62.96	2.59	11.04	0.18
Towing Hitch	65.93	2.71	14.13	0.21
Rear Doors	77	3.17	28.09	0.36
Wheels	102.25	4.20	68.89	0.67
Front Doors	116.66	4.80	92.53	0.79
Fenders	128.32	5.28	134.87	1.05
Front/Rear Seat & Console	157.56	6.48	272.57	1.73
Steering Column Assy	160.78	6.61	287.90	1.79
Pickup Box	204.74	8.42	498.35	2.43
Tailgate	213.14	8.76	538.55	2.53
Instrument Panel	218.66	8.99	565.06	2.58
Instrument Panel Plastic Parts	221.57	9.11	580.49	2.62
Cab	304.97	12.54	1,047.35	3.43
Radiator Support	310.87	12.78	1,095.34	3.52
Powertrain	425.82	17.51	1246.68	2.93

A fitted curve was developed based on the above listed mass reduction points to derive cost per kilogram at distinct mass reduction points. The current curve shows costs per kilogram approximately six times as expensive for 5 percent mass reduction (MR1) than in the NPRM, and approximately twice as expensive per kilogram for 7.5 percent mass reduction (MR2), which explains the reduction in mass reduction in the current analysis relative to the NPRM.

D. NHTSA CAFE Model Analysis of the Regulatory Alternatives for HD Pickups and Vans: Method A

EPCA and EISA require NHTSA to “implement a commercial medium- and heavy-duty on-highway vehicle and work truck fuel efficiency improvement program designed to achieve the maximum feasible improvement” and to establish corresponding fuel consumption standards “that are appropriate, cost-effective, and technologically feasible.”⁵⁰¹ For both the NPRM and the current analysis of potential standards for HD pickups and vans, NHTSA applied NHTSA’s CAFE Compliance and Effects Modeling System (sometimes referred to as “the CAFE model” or “the Volpe model”) to aid in determination of the maximally feasible standards. The subsequent analysis, referred to as “Method A,”

includes several updates to the model and to accompanying inputs, as discussed above in section 6.C. The “Method A” results are used as the primary basis for NHTSA’s final determination of the suitability of the Phase 2 standards. Further discussion of the determination are provided after the discussion of the “Method A” modeling results in Section 6.C.(9) of this document.

(1) Baseline Costs Across Manufacturers

As in the NPRM, the main analysis of Method A considers costs, benefits and other effects of regulatory alternatives relative to the dynamic baseline—or a baseline which assumes that manufacturers will apply all technologies with associated cost that pays back from retail-priced fuel savings within 6 months of purchase. The assumption is that consumers are willing to pay additional technology costs that return in fuel savings within 6-months of purchase, and that as a result, manufacturers will adopt these technologies regardless of fuel efficiency standards. We considered alternative runs with voluntary overcompliance of technologies with a payback period of 0-months (manufacturers will not voluntarily overcomply if there is a cost associated with a technology), 12-months, 18-months, and 24-months in the sensitivity analysis.

Before considering the effects of increases in the standards, it is important to discuss the baseline costs. These costs are assumed to be incurred even if no additional regulatory action is taken to increase standards beyond the existing MY 2018 standards. Table VI–12 shows the baseline average and total technology costs for each manufacturer in the heavy duty market, and for the heavy duty industry as a whole for the MY 2021 fleet (cost increases relative to the MY 2015 fleet). The updated CAFE model suggests that under no further increases to stringency beyond MY 2018, manufacturers would spend \$136 million—an industry average of \$180 per vehicle—on technologies that improve fuel economy in MY 2021. The additional baseline costs are not distributed across all manufacturers proportional to their fleet size. The average technology costs of an individual manufacturer fleet range from \$80 per vehicle for Fiat/Chrysler to \$350 per vehicle for General Motors. In order to explain this heterogeneity it is important to consider the sources of increased technology costs: compliance actions, inheritance from heavy duty vehicles, spillover inheritance from the light-duty vehicles, and voluntary overcompliance.

TABLE VI–12—MY 2021 COSTS (2013\$) UNDER ALTERNATIVE 1b (CENTRAL BASELINE) FOR 2b3 MARKET

Manufacturer	Average per vehicle technology cost (2013\$)	Total technology cost (million 2013\$)	Estimated MY 2015 fuel consumption (g/100 mi)	Estimated MY 2018 standard (g/100 mi)
Daimler	150	3	4.50	4.84
FCA	80	10	6.23	5.95
Ford	90	33	6.00	5.76
GM	350	86	6.52	5.94
Nissan	230	3	6.01	5.63
Industry	180	136	6.18	5.83

One reason manufacturers incur technology costs in the baseline for MY 2021 vehicles is to achieve compliance with Phase 1 standards, which end their stringency increases in MY 2018. Manufacturers will have different standards and different starting positions relative to these standards. In order to indicate which manufacturers make compliance actions which increase their baseline technology costs, Table VI–12 includes the MY 2015 estimated average fuel consumption and the estimated MY 2018 fuel consumption standard—manufacturers

with higher average fuel consumption in MY 2015 than the estimated MY 2018 fuel consumption standard, will apply technology costs to comply with the final MY 2018 standards. The fuel consumption standards are determined by setting work factor based targets and computing the manufacturer’s sales-weighted average of these targets. While the individual vehicle targets based on work factor are the same for all vehicles of the same work factor for model years 2018 and beyond, the overall fuel efficiency standard for a manufacturer may change from model year to model

year with changes to the work factors of individual vehicle models, as well as changes in relative production volumes of each vehicle model. The model does not capture all means by which a manufacturer’s average fuel efficiency standard may change under the MY 2018 attribute-based standards, but does capture changes to work factor—and therefore individual vehicle targets—due to application of mass reduction. The model also predicts changes to the fleet mix of each manufacturer using inputs created from AEO2015 and 2015 IHS/Polk production projections. The

⁵⁰¹ 49 U.S.C. 32902(k)(2).

technology cost for a manufacturer to meet MY 2018 standards is primarily driven by the fuel consumption gap between the MY 2015 (baseline) compliance level and the 2018 standard. From Table VI.4 it can be seen that only Daimler meets its most-stringent fuel consumption standard in 2015 and does not have to apply technology in the baseline to comply with Phase 1 standards.

A second source of technology costs is from inheritance; vehicles with shared platforms are assumed to inherit technologies applied to the platform leader at their next redesign or refresh to avoid creating a new body or engine platform,⁵⁰² even if these actions are no longer necessary to reach compliance. Manufacturers produce a limited set of engine and body platforms as a strategy to reduce their costs; there is no reason to indicate they will modify this strategy to comply with standards, for this reason this is an important constraint in the CAFE model. A similar source of technology costs are costs associated with spillover from the light-duty MY 2017–2021 standards. Regulatory agencies distinctly define the heavy duty and light duty classes, but from the manufacturer perspective these classes are not clearly delineated. They share some engine and body platforms across regulatory classes, and sometimes the most cost-effective choice to comply with standards will involve making changes to these shared platforms. Comments in the NPRM recommended

that we run the model with the ability to capture this spillover effect between the light-duty and heavy-duty fleets—in response to these comments, in the current analysis we run the two fleets together with all existing standards from the light-duty fleet included for all scenarios. Since the MY 2017–2021 light-duty CAFE standards are final, these and their effects are included in the baseline of the model—they will be in effect whether or not additional action is taken with heavy-duty standards. While we have included the ability for the standards from one fleet to affect the other, our modeling has shown that the spillover effect from the light-duty fleet into the heavy-duty fleet, and from the heavy-duty fleet into the light-duty fleet is small. We hope to further develop the model's ability to capture the spillover effects in future versions of the model.

The final way that manufacturers might accrue additional technology costs in the MY 2021 dynamic baseline scenario is through voluntary overcompliance. As already discussed: In the baseline case of the central analysis it is assumed that manufacturers will apply technologies which payback in fuel savings within 6 months of operation, regardless of whether or not the standards increase in stringency. Depending on the existing technologies and vehicles in a manufacturer's fleet, they may voluntarily overcomply by adding different technologies, or none at all.

The MY 2021 costs of the dynamic baseline scenario are lower in the updated analysis than they were in the

NPRM for all manufacturers other than Nissan and Daimler. The average technology costs across the industry are less than half the NPRM costs—dropping from \$440/vehicle to \$180/vehicle. The largest drop in average costs across the manufacturers is for GM; their costs dropped from \$780/vehicle to \$350/vehicle. The modeled costs for Nissan dropped from \$280 to \$230, and for FCA, from \$280 to \$80.

While considering MY 2021 allows for comparison to the NPRM analysis, not all baseline costs are incurred in MY 2021. Figure VI–8 shows the baseline total technology costs, and Figure VI–9, the average technology costs, by manufacturer for all model years. Like the NPRM analysis assumes manufacturers will likely apply most technologies as part of vehicle redesign or freshening; as a result their technology application comes in discrete blocks. GM applies \$20 million in total technology for their MY 2016 fleet, and an additional \$60 million in for MY 2018—their total technology costs vary slightly after this point with the projection of their fleet size and with the effects of technology learning. Similarly, Ford applies \$30 million for MY 2017 and an additional \$80 million in 2027. Chrysler/Fiat, Daimler, and Nissan apply technology in only one year—Chrysler/Fiat applies \$11 million in MY 2018, Daimler \$3 million for MY 2020, and Nissan \$3 million for MY 2021. While the total technology costs vary between manufacturers, the per-vehicle baseline costs range between \$0–\$350 for all manufacturers and model years.

⁵⁰² For a more complete discussion of inheritance in the model see Chapter 6, Section C.

Figure VI-8 Total Annual Baseline Technology Costs (million 2013\$) by Model Year and Manufacturer

Figure VI-9 Per Vehicle Baseline Technology Costs (million 2013\$) by Model Year and Manufacturer

(2) Relevant Model Updates

There are changes to model that help explain the decrease in baseline technology costs for the current

analysis. The current analysis uses the synergies simulated by Argonne for the light-duty fleet, while the NPRM analysis uses a limited set of synergy values (also initially estimated for the

light-duty fleet. The changes in these synergy factors could impact which technologies are chosen, and how effective the model calculates them to

be.⁵⁰³ Changes to the model input costs from the NPRM to the current analysis could also change which technologies get picked by the model, and the projected costs. One of the major changes to costs is a switch from the ICM cost mark-up methodology used in the NPRM to the RPE cost mark-up methodology of the current analysis.⁵⁰⁴ A more specific change to the input costs is a change to the mass reduction curve to be based off of the newer 2014 Silverado study, which suggests that 5 percent and 10 percent mass reduction is significantly more expensive than was assumed in the NPRM.⁵⁰⁵

The final major input change is that the current model uses the 2015 fleet as its reference point, while the NPRM uses the 2014 fleet. This affects the starting point of each manufacturer in the model, and could change their predicted standard (through changes in sales mix and work factor). In order to consider the impacts of using the 2015

reference fleet it is helpful to consider the sales-weighted fuel economy and work factor distributions across the two reference fleets.

Figure VI-10 shows the sales-weighted empirical cumulative distribution function (CDF) for GM's work factor and fuel economy for the two reference fleets. The dashed line shows the values for the 2014 reference fleet, and the solid, for the 2015 reference fleet. The y-axis shows the cumulative share of the manufacturer's fleet against the two measures. For GM, the work factor CDF shifted to the right for work factors between 3500 and 5500, suggesting that the proportion of the fleet with work factors in this range increased in the GM fleet. Since increases in work factor will decrease the target value for individual vehicles, this average change in work factor decreases GM's initial CAFE standard.

It should also be noted that some methods of increasing work factor

(mainly, decreasing curb weight) can increase the fuel efficiency of a vehicle, while others (increasing the power) can decrease fuel efficiency. The empirical CDF for GM's sales-weighted fuel consumption shows GM's 2015 fleet as having more vehicles with fuel consumption below 6.3 gal/100 mi, fewer with fuel consumption around 6.3 gal/100 mi, significantly more vehicles with fuel consumption around 7.0 gal/100 mi. The average fuel consumption of GM's 2014 fleet was 6.27 gal/100 mi, where the average fuel consumption of GM's 2015 fleet is 6.52 gal/100 mi. The overall increase in GM's average fuel consumption diminishes the effect of the increase in work factor from MY 2014 to MY 2015 at improving their starting position in MY 2015 relative to MY 2014—their MY 2015 standard using the 2014 fleet was 6.36, and using the 2014 fleet and is 6.59. Considering this, their initial shortfall is about the same using either reference fleet.

Figure VI-10 2014 vs. 2015 Reference Fleet Work Factor and Fuel Efficiency for General Motors

Figure VI-11 shows the same for Ford. There is a similar pattern of a higher proportion of heavy duty vehicles in Ford's fleet with work factors between 3500 and 5000. This will decrease Ford's initial standard in the model. Ford also shows a decrease in the proportion of heavy duty vehicles

with higher fuel consumption, which will result in an overall lower fuel consumption for the 2015 fleet. The result is that Ford will start with a lower standard by using the 2015 fleet rather than the 2014 fleet, and start with a higher fuel efficiency level—both of which will work in the same direction

to decrease Ford's shortfall to MY 2018 standards. This suggests that Ford will not need to apply as much technology to comply, and helps to explain their lower baseline technology costs in the current analysis.

⁵⁰³ For a more complete discussion of the changes to the Argonne simulation synergies see Chapter 6, Section C.

⁵⁰⁴ For further discussion on the switch from ICM to RPE for the final analysis see Chapter 6, Section C.

⁵⁰⁵ More discussion of the change in mass reduction curves is present in Chapter 6, Section C.

Figure VI-11 2014 vs. 2015 Reference Fleet Work Factor and Fuel Economy for Ford

Figure VI-12 shows the cumulative distribution function for the work factor of Fiat/Chrysler. Although there is some increase in the left tail of the distribution of FCA's work factor for MY 2015 relative to MY 2014, it is smaller

than for the Ford and GM fleets. The CDF of fuel efficiency also shows that Fiat/Chrysler shows nearly identical distribution of fuel consumption between the 2014 and 2015 fleets. These two factors combine to explain why

Fiat/Chrysler did not show increases in costs from the NPRM to the current analysis—they did not have as much of a change in shortfall to MY 2018 standards as both GM and Ford.

Figure VI-12 2014 vs. 2015 Reference Fleet Work Factor and Fuel Economy for Fiat/Chrysler

Figure VI-13 shows the same empirical distribution functions for Nissan. Both the distribution of work

factor and fuel consumption are comparable for Nissan's 2014 and 2015 fleets. This helps explain the small

change in Nissan's baseline costs between the two analyses.

Figure VI-13 2014 vs. 2015 Reference Fleet Work Factor and Fuel Economy for Nissan

Figure VI-14 shows the cumulative distribution function for work factor and fuel consumption for Daimler for both the 2014 and 2015 fleets. The distribution of work factor shifted right for work factors above 3500. The fuel

consumption curve shifted right for all fuel consumptions. This suggests that Daimler will face a lower standard using the 2015 reference fleet, but that they may also start with a lower initial fuel efficiency level. The change to the 2015

reference fleet does not have clear implications on the relative starting point of Daimler in the analysis relative to the NPRM analysis.

Figure VI-14 2014 vs. 2015 Reference Fleet Work Factor and Fuel Economy for Daimler

(3) Industry-Level Results of Regulatory Alternatives

Table VI-13, below, summarizes the stringency of standards, the estimated required fuel efficiency the estimated achieved fuel efficiency, as well as the impacts of each alternative for the

overall industry for MY 2030. Using the updated fleet and analysis, the MY 2030 stringency is slightly less than in the NPRM (4.91 gallons/100 mile in today's analysis compared to 4.86 gallons/100 mile in the NPRM for the preferred alternative). As has been noted, the

standards are set based in part on the work factor of vehicles; by changing the average work factor of their fleet, manufacturers can change the average stringency of their standard. While the model does not simulate changes to work factor which would increase the

power or GVWR, it does simulate changes in work factor due to mass reduction. By lowering the curb weight and holding power constant, manufacturers can increase the payload of a vehicle; since payload is a component in calculating the work factor, by lowering curb weight

manufacturers can increase their work factor for a vehicle model and reduce its target. However, the average absolute and proportional curb weight reduction in the current analysis is less than it was in the NPRM analysis across all alternatives, which can be explained by the higher mass reduction costs under

the current curve. This suggests that the change in the average overall industry standard in today's analysis is likely due in major part to changes in the work factor between the 2014 and 2015 reference fleet, and not to changes in the work factor simulated within the model runs.

TABLE VI-13—SUMMARY OF IMPACTS ON THE MY 2030 HD INDUSTRY FLEET (VS. ALTERNATIVE 1b)

Alternative	2	3	4	5
Stringency of Standards				
Annual Increase in Stringency Beginning in MY 2021	2.0%	2.5%	3.5%	4.0%
Increases Until	MY 2025	MY 2027	MY 2025	MY 2025

Average Vehicle (\$)	\$500	\$1470	\$1480	\$1890
Payback Period (m) ^b	19	30	31	33

Notes:

^a This increase in stringency is based on the estimated percentage change in fuel consumption (gal/100mi) stringency projected by the model for the MY 2030 fleet under the final Phase 2 standards relative to the continuation of Phase 1 standards. Note that if manufacturers' have applied mass reduction to an individual vehicle model in the CAFE model that this will increase the work factor of that vehicle in the model, and make the individual target less stringent. Thus, where any mass reduction is applied in the model, the total increase in stringency of the fleet presented here will be lower than the total stringency increase of the fleet if no mass reduction were applied.

^b Here payback period is calculated using estimated undiscounted retail fuel savings and the initial technology costs for MY 2030.

Today's Method A analysis using the updated version of the CAFE model and updated inputs shows that regulatory Alternatives 3 and 4 could be met with a small application of strong (P2) HEVs. However, Alternative 5 could be met with the considerably greater application of strong HEVs. Although there is some increase in the penetration rates between alternatives as stringency

increases, the current analysis suggests that under all alternatives, nearly all of the MY 2030 heavy-duty fleet could use 8-speed transmissions, VVT/VVL improvements and turbo-charged engines with application across more than half of the fleet, direct injection could be present in a quarter of the fleet, and cylinder deactivation could play a minor part in the HD fleet. EPS and

improved electrical accessories vary more between alternatives; present in 52 percent of the fleet in Alternative 2, 80 percent in Alternatives 3 and 4, and 96 percent in Alternative 5. Aerodynamic improvements and mass reduction follow a similar pattern; with a larger penetration of these technologies with Alternative 3 than with Alternative 2, a similar penetration under Alternatives 3

and 4, and a higher in penetration in Alternative 5.

A way to measure the cost-effectiveness of the technologies on consumers is to look at the payback period. In this context, the payback period is defined as the number of months of driving it will take a consumer to earn back the increased technology costs by the amount they save in fuel by driving a more fuel efficient vehicle. Under the current analysis, the average additional technology cost will payback in fuel savings in under 17 months for Alternative 2, 27 months for Alternatives 3 and 4, and 30 months for Alternative 5. It is important to note that there are inputs other than the cost and effectiveness of technologies which could affect the payback period; the fuel prices and mileage accumulation schedules will affect how quickly the cost of a fuel-saving technology pays back.

The current analysis uses updated fuel price estimates from AEO 2015 that are lower than in the NPRM analysis. Lower fuel prices will decrease the absolute amount of fuel savings (assuming the same number of gallons is consumed) and increase the payback period if the technologies, their cost, and their effectiveness are unchanged. Further, we have updated the vehicle use schedule (vehicle miles traveled, or VMT) based on actual vehicle odometer readings from IHS/Polk data as shown in Figure VI.6 While the overall survival-weighted schedules show 6.5

percent fewer lifetime miles for heavy-duty vehicles, they show more annual miles driven for the first 5-years of use for heavy-duty vehicles. The result is that the overall lifetime fuel savings will decrease, but the fuel savings will be higher for the first 5 years. Since the payback periods under both analyses are shorter than 5 years, using the updated vehicle schedules will show a shorter payback period (if other factors are unchanged) than in the NPRM analysis. The changes in fuel prices and the change in the mileage accumulation schedule work in opposite directions on the payback period; the total change in payback period is attributable to both of these input changes as well as to the changes in the cost⁵⁰⁶ and effectiveness⁵⁰⁷ of the different technology inputs, and the changes in the reference fleet.

Industry costs in MY 2030 provide one perspective on technology costs. Industry cost in each model year provides additional perspective on the timing, pace and the amount of resources and spending that would need to be allocated to implement technologies and is important in the consideration of the feasibility of the

⁵⁰⁶ The costs now use RPE rather than ICM, and we updated the mass reduction curve to the 2014 Silverado.

⁵⁰⁷ Nominal effectiveness input values are as for the NPRM analysis. Synergy factors applied to adjust fuel consumption impacts for specific combinations of technologies reflect current vehicle simulation work conducted for NHTSA by Argonne National Laboratory.

alternatives. Figures Figure VI–15 and Figure VI–16 show the total and average additional and total additional technology costs for the industry by model year and alternative. Note that the trend of the total and average costs are very similar, this is because the fleets size the AEO projections suggest a relatively constant fleet size during the considered MY's. The total and average technology costs increase with alternative stringency. It is important to note that Alternatives 3 and 4 both increase total stringency for the MY 2030 industry fleet by 15.6 percent. Also note that these estimations of stringency increases include the model projections of how the application of mass reduction will alter work factor and individual vehicle targets.⁵⁰⁸ The annual average and total technology costs of Alternative 3 approach those of Alternative 4 by MY 2029 when both alternatives have reached maximum stringency. If manufacturers are to reach the same stringency level over a longer horizon, they will likely make similar technology choices, but be given longer to implement them. This will make the total technology costs lower, but should unsurprisingly make the marginal technology costs for model years where both standards have matured very similar.

BILLING CODE 6560–50–P

⁵⁰⁸ The final Phase 2 standard target curves increase in stringency by 16.2 percent compared to final Phase 1 standards, as discussed in section VI.B.

Figure VI-15 Industry Total Technology Cost Increase by Model Year and Alternative

Figure VI-16 Industry Average Technology Cost Increase by Model Year and Alternative

The average incremental industry technology costs mature to around \$500 under Alternative 2, \$1500 under Alternatives 3 and 4, and \$1900 under Alternative 5. Figure VI-17 shows the

cumulative total industry costs by model year fleet. \$4.2 billion in additional technology costs for model years 2016–2030 are associated with Alternative 2, \$9.9 billion with

Alternative 3, \$11.4 billion with Alternative 4, and \$14.9 billion with Alternative 5. While the marginal technology costs of Alternative 3 approach those of Alternative 4 as the

total stringencies converge, the total costs of Alternative 4 are \$1.5 billion more by MY 2030. It is particularly noteworthy that costs and the rate of increase in costs would be significantly different in the MYs 2017–2021 timeframe among the alternatives. This

identifies the significant differences in the resources and capital that would be required to implement the technologies required to comply with each of the alternatives during this period, as well as the reduction in lead time to implement the technologies which

increases reliability risk. These differences are an important consideration for the feasibility of the alternatives and for the selection of the final standards, as discussed further below.

Figure VI-17 Industry Cumulative Total Technology Cost Increase by Model Year and Alternative

BILLING CODE 6560-50-C

(4) Manufacturer-Specific Results of Regulatory Alternatives

In addition to varying across scenario and model year, the impacts of the standards vary across manufacturers. Manufacturers will have different compliance strategies based on which technologies they have already invested

in, in both their heavy-duty and light-duty fleets, and based on the effectiveness of new technology applications specific to the vehicles in their heavy duty fleets. Table VI-14 summarizes the initial technology utilization in the 2015 fleet by manufacturer. Ford uses direct injection for 8 percent of their fleet, cylinder deactivation for 13 percent of their fleet,

and turbo-charged engines for 8 percent of their fleet. Daimler has already invested to equip all of its fleet with 8-speed automatic transmissions. These differences in initial technology levels affect the new investments each manufacturer would need to further improve the fuel efficiency of their fleets.

TABLE VI-14—SUMMARY OF MY 2015 REFERENCE FLEET TECHNOLOGY PENETRATION

Technology	Technology Penetration (percent)					
	GM	Ford	FCA	Daimler	Nissan	Industry
Cylinder Deactivation	0	0	13	0	0	2
Direct Injection Engine	0	8	0	0	0	4
Turbo Charged Engine	0	8	0	0	0	4
8 Speed Auto. Trans.	0	0	0	100	0	3
EPS, Accessories	0	0	0	0	0	0
12V Stop-start	0	0	0	0	0	0
Strong Hybrid	0	0	0	0	0	0
Aero. Improvements	0	0	0	0	0	0

Table VI–15 summarizes the alternatives, and a technology pathway General Motors could use to comply with each of the alternatives. The pathway includes implementing 8 speed automatic transmissions across its entire fleet. For Alternatives 2 and 3, no stop-start or HEVs are added to GM's fleet, for Alternative 4, 1 percent of GM's fleet uses stop-start, and for Alternative 5, 2 percent uses stop-start and 13 percent are HEVs. For all alternatives, nearly all

of the GM's fleet would use electric power steering and improved electric accessories.

For all alternatives, VVT/VVL is applied to 65 percent of its engines. For Alternative 2, none of its engines get direct injection and 43 percent get turbocharging and downsizing, while for Alternatives 3–5, direct injection is applied to 28 percent of its engines and turbocharging and downsizing is applied to 61 percent of its engines. For

all alternatives, all of GM's fleet gets aerodynamic improvements. The average mass reduction is 52 lbs. (0.78 percent of the average curb weight) under Alternative 2, and 350–380 lbs. (5.2–5.7 percent of the average curb weight) under Alternatives 3–5. Similar technology is applied for Alternatives 3 and 4 in MY 2030, but there are significantly more strong hybrids under Alternative 5.

TABLE VI–15—SUMMARY IMPACTS ON GENERAL MOTORS HD FLEET BY ALTERNATIVE (VS. ALTERNATIVE 1b)

Alternative	2	3	4	5

Mass Reduction (vs. No-Action)				
Curb Weight Mass Reduction (lb.)	52	384	384	340
Mass Reduction (percent of curb weight)	0.78	5.7	5.7	5.1

Note:

^a This increase in stringency is based on the estimated percentage change in fuel consumption (gal/100mi) stringency projected by the model for the MY 2030 fleet under the final Phase 2 standards relative to the continuation of Phase 1 standards. Note that if manufacturers' have applied mass reduction to an individual vehicle model in the CAFE model that this will increase the work factor of that vehicle in the model, and make the individual target less stringent. Thus, where any mass reduction is applied in the model, the total increase in stringency of the fleet presented here will be lower than the total stringency increase of the fleet if no mass reduction were applied.

Figure VI–18 and Figure VI–19 show the total and average incremental technology costs by alternative. Under Alternative 2 General Motors' incremental technology cost is \$140M in MY 2019, increasing to \$180M in MY 2021. The pathways for Alternatives 3 and 4 are very similar, which again should not be surprising given that the standards result in the same total

stringency increase in MY 2027 and beyond and the long redesign cycles in the segment. GM's incremental technology cost is \$190M in MY 2019, increasing to \$400M in MY 2021, and \$530M in MY 2028. Under Alternative 5 GM could have a similar compliance strategy as Alternative 3 and 4, but incremental technology cost is \$650M in MY 2028. The highest annual average

technology cost for GM is: \$750 under Alternative 2, \$1940 under Alternatives 3 and 4, and \$2370 under Alternative 5. In the case of GM, the added lead time of Alternative 4 does not significantly change the cost of their compliance strategy.

BILLING CODE 6560–50–P

Figure VI-18 Total Technology Cost Increase for General Motors by Model Year and Alternative

Figure VI-19 Average Technology Cost Increase for General Motors by Model Year and Alternative

Figure VI-20 shows the cumulative total incremental costs for GM under all alternatives. The total costs to comply

with Alternative 2 for GM for MY's 2016–2030 is \$2.1 billion, for

Alternatives 3 and 4 it is \$4.8 billion, and for Alternative 5 it is \$5.2 billion.

Figure VI-20 General Motors Cumulative Total Technology Cost Increase by Model Year and Alternative

BILLING CODE 6560-50-C

Table VI-16 gives the same summary of a potential compliance strategy for Ford's heavy-duty fleet. Similar to GM, to reach compliance Ford uses 8 speed automatic transmissions in their entire fleet. For Alternatives 3 and 4, Ford uses hybrid technologies in 4 percent of their fleet, and for Alternative 5, they use hybrid technologies in 7 percent of their fleet. In addition to strong hybrids, Ford uses 12v stop-start in 4 percent of their fleet in Alternative 4, and 12v stop-start in 19 percent of their fleet in Alternative 5. The compliance strategy in the NPRM analysis shows Ford using significantly more hybrids and 12v stop-start systems in Alternatives 4 and 5 than the current analysis which likely explains part of

the lowered cost for Ford in the current analysis.

Under the current analysis possible compliance strategy, the application of engine technologies for Ford come in discrete chunks, as with GM. Ford uses VVT/VVL in 58 percent of their fleet under all alternatives by MY 2030; they started with 8 percent direct-injection engines, and end with 27 percent; they also started with 8 percent turbo-charged engines, but end with 69 percent for all scenarios. The application of EPS and improved accessories vary across the compliance strategies of different regulatory alternatives; under Alternative 2, only 13 percent of Ford's fleet improves these electrical features, while under

Alternatives 3-4, 64 percent, and Alternative 5, 96 percent.

For body-platform technologies, Ford applies in discrete chunks to the same platforms across some Alternatives. They apply an average of 77 lb. (1.2 percent) mass reduction across their fleet in Alternative 2 and 132-142 lb. (2.0-2.2 percent) in Alternative 3-5. Progressively less mass reduction is applied under Alternatives 4 and 5—this is likely because more of the fleet was hybridized and mass reduction to small platforms was no longer necessary to comply. Aerodynamic improvements are not applied in Alternative 2, but are applied to 64 percent of the fleet in Alternative 3 and 4, and to all of the fleet in Alternative 5.

TABLE VI-16—SUMMARY OF IMPACTS ON FORD HD FLEET BY ALTERNATIVE (VS. ALTERNATIVE 1b)

Mass Reduction (percent of curb weight)	1.2	2.2	2.1	2.0

Note:

^aThis increase in stringency is based on the estimated percentage change in fuel consumption (gal/100mi) stringency projected by the model for the MY 2030 fleet under the final Phase 2 standards relative to the continuation of Phase 1 standards. Note that if manufacturers' have applied mass reduction to an individual vehicle model in the CAFE model that this will increase the work factor of that vehicle in the model, and make the individual target less stringent. Thus, where any mass reduction is applied in the model, the total increase in stringency of the fleet presented here will be lower than the total stringency increase of the fleet if no mass reduction were applied.

BILLING CODE 6560-50-P

Figure VI-21 and Figure VI-22 show the total and average incremental technology costs for Ford by alternative and model year. Ford adds \$80 million in technology costs for MY 2017 and an additional \$40 million in MY 2026 in Alternative 2. For the Preferred Alternative, Ford adds \$130 million in MY 2017 and an additional \$300 million in MY 2026. Under Alternative 4, Ford adds \$260 million in MY 2017 and \$180 million in MY 2026. Similar to the industry pattern, Ford's compliance strategy involves less annual technology costs early in Alternative 3 than Alternative 4, but

their technology costs converge under the two alternatives as the final stringency level is reached under Alternative 3 in MY 2027.

It is important to note that the increase in costs and rate of the increase in costs is significantly different for MY 2017 among the alternatives—with the incremental total cost increase for MY 2017 being double those of Alternative 3 for Alternative 4, and more than double for Alternative 5. MY 2017 is the first redesign year and Ford does not have another scheduled redesign until MY 2026. Under the additional lead time of Alternative 3, the majority of Ford's cost increases occur in the MY

2026 redesign, while Alternatives 4 and 5 put most of the cost burden to reach compliance on the MY 2017 redesign (or would require an additional redesign be added between MY 2017 and 2026).

NHTSA judges the lack of lead time would make Alternatives 4 and 5 beyond maximum feasibility for Ford because its designs for MY 2017 are essentially complete and substantial resources and very high costs would be required to add another vehicle redesign between MY 2017 and MY 2026 to implement the technologies that would be needed to comply with those alternatives.

BILLING CODE 6560-50-P

Figure VI-21 Total Technology Cost Increase for Ford by Model Year and Alternative

Figure VI-22 Average Technology Cost Increase for Ford by Model Year and Alternative

Figure VI-23 below shows the cumulative total costs for Ford under all action alternatives. The total costs for MY's 2015–2030 under Alternative 2 are \$1.3 billion, under Alternative 3 they

are \$3.4 billion, for Alternative 4 they are \$4.5 billion, and finally for Alternative 5 they are \$6.7 billion. This further illustrates the point that manufacturers act to minimize costs

over multiple model years. The added lead time from Alternative 4 allows them to delay some actions, which will allow them more time to make sure that they are well-implemented.

Figure VI-23 Ford Cumulative Technology Cost Increase by Model Year and Alternative

BILLING CODE 6560-50-C

Table VI-17 shows the MY 2030 summary for Fiat/Chrysler. Fiat/Chrysler is the only manufacturer which uses cylinder deactivation in their reference fleet, and they are the only manufacturer to use cylinder deactivation as a part of their possible compliance strategy. Under all scenarios, FCA increases their initial cylinder deactivation utilization of 13 percent to 24 percent. Under all scenarios turbo-charged engines are applied to 76 percent of FCA's fleet by

MY 2030. Other technologies are applied to the FCA equally across all scenarios; 37 percent of their fleet uses VVT and/or VVL, and 64 percent uses 8-speed automatic transmissions under all scenarios.

The additional stringency from Alternative 2 to Alternatives 3-5 results in other increased technology applications in the FCA fleet. Under Alternatives 3-5, the presence of EPS/electrical accessories increases from the 82 percent to the entirety of the FCA fleet. Similarly, increased aerodynamic

improvements increase from 84 percent of the fleet to all of it. Finally, 12v stop-start enters 3 percent of the fleet under Alternatives 3-5. Alternatives 3 and 4 look much the same, except that Alternative 3 is the only alternative to use any (1 percent) SHEV-P2 hybrids. Alternative 5 uses twice as much mass reduction than Alternatives 3-4; it uses 37 percent direct injection versus the 24 percent in Alternatives 2-4. The resulting costs are comparable under Alternatives 3 and 4, and almost 50 percent higher under Alternative 5.

TABLE VI-17—SUMMARY OF IMPACTS ON FIAT/CHRYSLER HD FLEET BY ALTERNATIVE (VS. ALTERNATIVE 1b)

Note:

^aThis increase in stringency is based on the estimated percentage change in fuel consumption (gal/100mi) stringency projected by the model for the MY 2030 fleet under the final Phase 2 standards relative to the continuation of Phase 1 standards. Note that if manufacturers' have applied mass reduction to an individual vehicle model in the CAFE model that this will increase the work factor of that vehicle in the model, and make the individual target less stringent. Thus, where any mass reduction is applied in the model, the total increase in stringency of the fleet presented here will be lower than the total stringency increase of the fleet if no mass reduction were applied.

Figures Figure VI-24 and Figure VI-25 show the incremental total and average technology costs for Chrysler/Fiat by model year and regulatory stringency. Chrysler/Fiat shows more technology costs for higher stringency alternatives, with annual technology costs of Alternative 3 approaching Alternative 4 annual technology costs as the Alternative 3 approaches the final stringency level in MY 2027. Under all alternatives Chrysler/Fiat incurs increased technology costs starting in MY 2018 and MY 2025, because they are estimated redesign years. The maximum annual technology costs for Chrysler are \$92M in Alternative 2,

\$213M in Alternative 3, \$227M in Alternative 4, and \$330M in Alternative 5. This results in average technology costs of: \$680, \$1640, \$1690, and \$2460, respectively.

As with Ford, the costs and the rate of increase in costs are significantly different in the MY 2018 timeframe among the alternatives, because MY 2018 is the first estimated model year for redesign, and the next estimated redesign opportunity is in MY 2025. Figure identifies the significant differences in the resources and capital that would be required to implement the technologies required to comply with each of the alternatives—with the

estimated MY 2018 technology cost increases being 48M under Alternative 3, 78M under Alternative 4, and 112M under Alternative 5. NHTSA judges the short lead time would make Alternatives 4 and 5 beyond maximum feasible for FCA because its designs for MY 2018 are nearing completion and substantial resources and very high costs would be required to add another vehicle redesign between MY 2018 and MY 2025 to implement the technologies that would be needed to comply with those alternatives.

BILLING CODE 6560-50-P

Figure VI-24 Total Technology Cost Increase for Fiat/Chrysler by Model Year and Alternative

Figure VI-25 Average Technology Cost Increase for Fiat/Chrysler by Model Year and Alternative

The cumulative technology costs attributable to the action alternatives for FCA are represented in Figure VI-26

below. The total costs for MY's 2016–2030 under alter Alternative 2 are \$750 million, under Alternative 3, they are

\$1.5 billion, for Alternative 4, \$1.8 billion, and for Alternative 5 they are \$2.6 billion.

Figure VI-26 Fiat/Chrysler Cumulative Technology Cost Increase by Model Year and Alternative

BILLING CODE 6560-50-C

Table VI-18 shows the manufacturer-specific MY 2030 summary for Nissan. Nissan's 2015 reference fleet uses VVT and/or VVL on all of their heavy-duty vehicles. Their fleet uses two engines on only one body-style platform. As a result, technologies applied to Nissan's fleet are applied to large proportions of their fleet. Under all scenarios, their entire fleet gains 8-speed automatic transmissions. Under Alternatives 3-5, all of their fleet gets level-2 body-level aerodynamic improvements and all of their fleet gets electric accessory and/or EPS improvements. Under Alternatives 2, 4, and 5, one of Nissan's two heavy-duty engines gets direct-injection, while under Alternative 3, both engines get the technology. Direct injection of their

entire fleet is the most cost-effective way to reach compliance under Alternative 2, applying 5 percent mass reduction to their entire fleet and direct injection of one of their engines is the most cost-effective strategy under Alternative 4, and applying 10 percent mass reduction to their entire fleet, direct injection to one of their engines, and making their other engine hybrid is the most cost-effective strategy under Alternative 5.

Note that without a change in the work factor or fleet mix, a manufacturer will face the same MY 2030 standard under Alternatives 3 and 4, and a more stringent standard under Alternative 5. However, by applying 5 percent mass reduction in Alternative 4, Nissan is able to reduce their standard by .27

MPG, and by applying 10 percent mass reduction in Alternative 5 to have the same MY 2030 standard under Alternatives 3 and 5. The result is that the CAFE level for Nissan is highest under Alternative 2, where direct injection of their entire fleet is the most cost-effective compliance strategy. We assume that manufacturers are able to make technologies more cost-effectively the longer they are on the market—this is called "learning." A likely reason that the model prefers direct injection in Alternative 3 but not in Alternatives 4 and 5, is that the longer horizon of the stringency increase (until MY 2027) results in direct injection that is more cost-effective than the shorter time span of Alternatives 4 and 5.

Note:

^aThis increase in stringency is based on the estimated percentage change in fuel consumption (gal/100mi) stringency projected by the model for the MY 2030 fleet under the final Phase 2 standards relative to the continuation of Phase 1 standards. Note that if manufacturers' have applied mass reduction to an individual vehicle model in the CAFE model that this will increase the work factor of that vehicle in the model, and make the individual target less stringent. Thus, where any mass reduction is applied in the model, the total increase in stringency of the fleet presented here will be lower than the total stringency increase of the fleet if no mass reduction were applied.

Figures Figure VI-27 and Figure VI-28 show the total and average incremental technology costs for Nissan across the different regulatory alternatives. Nissan applies technology in all alternatives in MY 2021; this is a redesign year for much of their fleet. As might be expected, they incur less

technology cost in less stringent scenarios at this redesign. However, under Alternative 3 they apply more technology in MY 2029, making their marginal technology costs under Alternative 3 for MY 2029 and after higher than the marginal technology costs under Alternative 4. They incur

less technology costs in the early years and more in MY's 2029 and beyond. In order to explain why the model predicts this action of Nissan it is useful to look at the cumulative total incremental costs in Figure VI-29.

BILLING CODE 6560-50-P

Figure VI-27 Total Technology Cost Increase for Nissan by Model Year and Alternative

Figure VI-28 Average Technology Cost Increase for Nissan by Model Year and Alternative

By incurring less technology cost early, and more technology cost later, Nissan has a lower cumulative total cost for MY's 2016–2030 under Alternative 3 than Alternative 4. The total cumulative

cost for MY's 2016–2030 of Alternative 2 is \$86 million, \$178 million for Alternative 3, \$258 for Alternative 4, and \$387 for Alternative 5. Since Nissan is trying to minimize their total cost

under all model years, and not their marginal cost under any single model year, the model chooses a compliance strategy in this case which shows higher marginal costs for Nissan in Alternative

3 than 4 for some model years, but

lower cumulative total costs over all model years.

Figure VI-29 Nissan Cumulative Technology Cost Increase by Model Year and Alternative

BILLING CODE 6560-50-C

Nissan's first redesign is in MY 2020, and they do not have another redesign scheduled until 2029. Under Alternative 4 and 5 all of their technological application is done in MY 2020, but under Alternative 3 the application can be spread out between the two redesign cycles. NHTSA judges the short lead time to apply technology would make Alternatives 4 and 5 beyond maximum feasibility for Nissan because it puts the burden of all technological application on the MY 2020 redesign. Substantial

resources and costs would be required to do so or to add another vehicle redesign between MY 2020 and MY 2029. Since manufacturers must spread out their capital for such deployment endeavors between the light and heavy duty fleets, the ability to spread costs between model years is important to consider.

Table VI-19 shows a MY 2030 summary for Daimler. Daimler came into the analysis with all of their fleet using 8-speed automatic transmissions. Their initial CAFE level in MY 2020 of

25.68 was sufficient to meet their standard under Alternatives 2-5. Their only action to turbo-charge all the engines in their fleet occurs in the dynamic baseline. As a result, no additional actions or costs are incurred under any of the alternatives. For this reason, a figure of their annual technology costs, nor their cumulative total technology costs has not been provided—if it were, it would be a horizontal line showing zero costs for all model years.

Mass Reduction (vs. No-Action)				
Curb Weight Mass Reduction (lb.)	0	0	0	0
Mass Reduction (percent of curb weight)	0	0	0	0

Note:

^aThis increase in stringency is based on the estimated percentage change in fuel consumption (gal/100mi) stringency projected by the model for the MY 2030 fleet under the final Phase 2 standards relative to the continuation of Phase 1 standards. Note that if manufacturers' have applied mass reduction to an individual vehicle model in the CAFE model that this will increase the work factor of that vehicle in the model, and make the individual target less stringent. Thus, where any mass reduction is applied in the model, the total increase in stringency of the fleet presented here will be lower than the total stringency increase of the fleet if no mass reduction were applied.

(5) Summary of Consumer/Operator Impacts

Table VI-20 summarizes the impacts of the regulation on the consumer/operator of the heavy-duty vehicles. Consumers of more fuel efficient vehicles will benefit in several ways: They will spend less on fuel to operate vehicles for the same amount of travel, some will drive more because their per-mile travel costs less, and they will spend less time refueling vehicles. In order to estimate the fuel savings for each regulatory alternative, future gasoline prices must be predicted and the rebound effect (per-mile elasticity of operating a vehicle) must be assumed to account for the cost of additional driving. In the main analysis, the rebound effect is assumed to be 10 percent, so that, for example, a 10 percent reduction in the per-mile travel costs will result in a 1 percent increase in the amount of miles driven. Since the literature has also supported other rebound effects, NHTSA tests several sensitivity cases assuming different rebounds: 5 percent, 15 percent, and 20 percent. Based on the average miles driven of 2b/3 vans and trucks, the expected lifetime fuel savings for a heavy-duty vehicle under the preferred scenario is \$3636.

The other benefits of to the consumer of increasing fuel economy are increased mobility and a decreased amount of time spent refueling the vehicle. Because increasing the

efficiency of a vehicle makes per-mile travel cheaper to the operator, consumers of these vehicles can travel more, at less than the total amount they are willing to pay—this increase in welfare that is not accounted for by the cost of travel is the consumer surplus. The estimated mobility benefit is \$394 under the preferred alternative. The avoided time refueling also has a value. In order to estimate this value we make several assumptions outlined in more detail of the NPRM description of the model assumptions (Section E). Over the lifetime of a MY 2030 vehicle, we estimate the refueling surplus at \$94 under the preferred alternative.

It is also important to note that the average manufacturer costs will not be spread proportionally across the fleet—some vehicles will have incurred more technology costs than others. How manufacturers distribute costs among models will largely depend on the elasticity of particular models and the importance of fleet mix in meeting standards and on total profits. Without privity to this sort of information, we use average technology cost increase as a proxy for measuring the industry and consumer costs across different scenarios. The average technology cost increase is \$1472 under the preferred alternative. We assume that all of this cost will be passed onto the consumer in the form of an increase in price. However, we also consider that an

increase in price will have other costs to the operator of the vehicle.

More expensive vehicles will have higher taxes/fees associated with their purchase, will be more expensive to insure (these costs are related to the purchase price or value of a vehicle) and will be more expensive to finance (higher loan values will be taken out which result in higher amounts paid in total interest). The total additional costs to the average consumer from the sum of these sources is \$589 under the preferred alternative. It is important to keep in mind that the additional cost to finance a more expensive vehicle will have different effects depending on the budget constraint of the consumer. For consumers who are budget-constrained, they will finance more of the vehicle and the costs of financing will be higher for these already-constrained consumers. For consumers who do not have to finance the vehicle, there will be no costs—and therefore, no additional costs—to finance the vehicle. Since budget-constrained consumers likely have a more elastic demand for new vehicles, the increase in price and the heterogeneous increase in financing might work in the same direction to price proportionally more of the most budget-constrained consumers out of the new vehicle market.

Considering all the costs and benefits the standards will have to the consumer, the result is a net benefit to the consumer under all the considered alternatives. The net benefit to the

consumer is \$2,063 under the preferred alternative, higher than the net benefit under alternative 4. The payback period is another measure of the effect of the

rule on consumers—for all alternatives the payback period is under 3 years—suggesting that consumers that own vehicles for at least 3 years will receive

a net benefit from the preferred regulatory action.

TABLE VI-20—SUMMARY OF CONSUMER/OPERATOR IMPACTS FOR MY 2030 (VS. ALTERNATIVE 1b)

Alternative	2	3	4	5
Alternative Stringency				
Annual Increase	2.0%	2.5%	3.5%	4.0%

Mobility Increase	220	394	390	453
Avoided Refueling	49	94	93	112
Average New Vehicle Purchase (vs. No-Action)				
Price Increase (\$)	496	1,472	1,481	1,893
Additional Costs (\$) ^a	103	306	336	393
Payback (months) ^b	20	33	33	38
Net Lifetime Consumer/Operator Benefits (vs. No-Action)				
Total Net Benefit (\$)	1,488	2,063	1,989	2,167

Notes:

^a Additional Costs include additional taxes, fees, maintenance costs, financing costs, and insurance costs incurred under the regulatory alternatives.

^b The payback period from the consumer perspective uses a 7% discount rate of retail fuel savings starting at the time of purchase. The cost increases paid back include: Technology costs, maintenance costs, taxes, and fees.

(6) Summary of Societal Impacts

Table VI-21 summarizes the overall societal impacts of the regulation under different scenarios (relative to the 1b baseline). Net social benefits increase with the stringency of the standards. The net benefits for the preferred alternative are \$18.8 billion. The largest

benefit of the program comes in the form of fuel savings. The fuel savings reported above do not include fuel tax savings, as taxes are considered a transfer, and not a loss, of societal well-being. The fuel savings are associated with a fuel security externality, which monetizes the economic risk associated

with potential fuel price spikes—as fewer gallons of oil are necessary for transportation, this risk decreases. The carbon externality represents the reduced cost of carbon damage when fuel economy increases (and carbon emissions decrease), and is also related directly with fuel savings.

TABLE VI-21—SUMMARY OF LIFETIME TOTAL SOCIETAL IMPACTS OF MY'S 2015–2029 (VS. ALTERNATIVE 1b)

Alternative	2	3	4	5

Total Social Cost	4.2	7.8	9.2	11.6
Total Social Benefit	16.5	26.6	30.3	34.5
Net Social Benefit	12.3	18.8	21.1	22.9

Increasing fuel economy decreases the cost of per-mile travel. Since this reduction in the cost of travel results in an increase of total travel, it also results in an increase of externalities associated with increased total VMT. Of these, the driving surplus represents the societal net increase in benefit from increased mobility consumer surplus—the sum of the benefit to all operators of increased travel which is not captured by the total cost of travel. Defined from the societal perspective, the refueling benefit is the sum of all the value of the time saved on refueling by increasing the average fuel efficiency of the heavy duty fleet. Congestion represents the societal cost of increases in congestion on the roads—the lost value of additional time spent in traffic. The crash externality is the cost of the damage done by the additional crashes that will happen with more VMT exposure, and the noise externality represents the cost of a change in noise related to increases in vehicle travel (in this analysis, it is negligible for all alternatives).

Some VMT-related externalities are not always positive or negative, but depend on the stringency of the standards. For this analysis the criteria pollutant externality is always a benefit, but this need not be the case. Reduction in overall fuel consumed reduces emissions associated with production and distribution of fuels. Increases in VMT will result in more emission of vehicle criteria pollutants and more associated damages. However, increasing fuel-economy through vehicle technologies, such as aerodynamics, mass reduction and improved tire rolling resistance, will result in a decrease in vehicle emissions of and damages from criteria pollutants. Shifts

in technologies towards electric and hybrid-electric alternatives can increase the emissions of certain pollutants, and reduce the emissions of others. The stringency increases considered in the heavy-duty analysis do not require these technologies to penetrate the market at such a level that this is visible in the results. For these reasons the externality associated with changes in criteria pollutant emissions is always positive for this analysis.

The vehicle mass reduction in HD pickup and vans is estimated to reduce the net incidence of highway fatalities. By reducing mass on some HD pickup and vans, the fatality rate associated with crashes involving at least one HD pickup or van vehicles decreases. However, the analysis anticipates that the indirect effect of the proposed standards, by reducing the operating costs, would lead to increased travel by HD pickups and vans and, therefore, more crashes involving these vehicles. The sign of the fatality externality varies with the stringency of the standards. Over the lifetime of MY's 2016–2029, for Alternative 2 it is estimated approximately 120 additional fatalities could occur relative to the 30,200 heavy-duty crash-related fatalities in the baseline. For Alternatives 3 and 4 we estimate approximately 50 additional fatalities relative to the no-action alternative. The additional risk of fatality is represented as a social cost in Alternatives 2–4. For Alternative 5 we estimate approximately 110 fewer fatalities (represented as a positive externality). For Alternatives 2–4, the effect of removing mass from the heavier vehicles is less than the effect of increased VMT-exposure; for Alternative 5, it is larger, and the

alternative could result in a decrease of fatalities.

The major direct costs of the program are increased technology costs and costs associated with the resultant increase in new vehicle prices and changes in technologies. The sum of technology costs across the industry increase under all increases of stringency, as do the increases in associated additional costs. Additional costs include: additional costs of maintenance associated with certain technologies. These costs will mostly be borne by the consumer, and paid back in the form of fuel savings.

(7) Summary of Environmental Impacts

In addition to modeling the societal impacts from a monetary standpoint, the CAFE model also considers the absolute change in the physical emissions of various criteria pollutants across the Alternatives. Table VI-22 summarizes the total environmental impacts from increased fuel efficiency of MYs 2016–2030, taking into consideration the reduction in emissions from increased efficiency, the additional emissions associated with the increased VMT from cheaper per-mile travel, and changes in emissions due to the production and distribution of heavy-duty vehicles. Across all scenarios, the absolute reduction in emissions increases. For context, the percentage change of emissions relative to the baseline emission levels is also provided. The proportional reduction in criteria pollutants greatly varies; the greenhouse gases—carbon dioxide, methane, and nitrous oxide—as well as the criteria pollutants—sulfur dioxide and diesel particulate matter—show the largest proportional reductions across all scenarios.

TABLE VI-22—SUMMARY OF LIFETIME EMISSION IMPACTS OF MY'S 2015–2029 (vs. ALTERNATIVE 1b)

(8) Sensitivity Analysis Evaluating Different Inputs to the NHTSA CAFE Model

This section describes some of the principal sensitivity results, obtained by running the various scenarios describing the policy alternatives with alternative inputs. OMB Circular A-4 indicates that “it is usually necessary to provide a sensitivity analysis to reveal whether, and to what extent, the results of the analysis are sensitive to plausible changes in the main assumptions and numeric inputs.”⁵⁰⁹ Considering this guidance, a number of sensitivity analyses were performed using analysis Method A to examine important assumptions and inputs, including the following, all of which are discussed in greater detail in the accompanying RIA:

1. *Payback Period*: In addition to the 0 and 6 month payback periods discussed above, also evaluated cases involving payback periods of 12, 18, and 24 months.

2. *Fuel Prices*: Evaluated cases involving fuel prices from the AEO 2015 low and high oil price scenarios. (See AEO-Low and AEO-High in the tables).

3. *Fuel Prices and Payback Period*: Evaluated one side case involving a 0 month payback period combined with fuel prices from the AEO 2015 low oil

price scenario, and one side case with a 24 month payback period combined with fuel prices from the AEO 2014 high oil price scenario.

4. *Benefits to Vehicle Buyers*: The main Method A analysis assumes there is no loss in value to owner/operators resulting from vehicles that have an increase in price and higher fuel economy. NHTSA performed this sensitivity analysis assuming that there is a 25, or 50 percent loss in value to owner/operators—equivalent to the assumption that owner/operators will only value the calculated benefits they will achieve at 75, or 50 percent, respectively, of the main analysis estimates. (These are labeled as 75pctOwner/Operator Benefit and 50pctOwner/Operator Benefit.)

5. *7 Pct Discount Rate*: The main analysis results are considered using either a 0 or 3 percent discount rate. We also considered an alternative case where future savings/costs are discounted 7 percent annually.

6. *Value of Avoided GHG Emissions*: Evaluated side cases involving lower and higher valuation of avoided CO₂ emissions, expressed as the social cost of carbon (SCC).

7. *Rebound Effect*: Evaluated side cases involving rebound effect values of 5 percent, 15 percent, and 25 percent. (These are labeled as 05PctReboundEffect,

15PctReboundEffect and 25PctReboundEffect).

8. *ICM-based Markup*: Evaluated a side case using a retail price equivalent (ICM) markup factor.

9. *Mass-Safety Effect*: Evaluated side cases with the mass-safety impact coefficient at the values defining the 5th and 95th percent points of the confidence interval estimated in the underlying statistical analysis. (These are labeled MassFatalityCoeff05pct and MassFatalityCoeff95pct).

10. *VMT Schedules*: Evaluated side cases considering the NHTS considered in the NPRM analysis as a high-VMT case, and another considered schedule as a low-VMT case.

11. *Strong HEVs*: Evaluated a side case in which strong HEVs were excluded from the set of technology estimated to be available for HD pickups and vans through model year 2030. As in Section VI.C. (8), this “no SHEV” case allowed turbocharging and downsizing on all GM vans to provide a lower-cost path for compliance.

Table VI-23, below, summarizes key metrics for each of the cases included in the sensitivity analysis using Method A for the alternative. The table reflects the percent change in the metrics (columns) relative to the main analysis, due to the particular sensitivity case (rows) for the alternative 3. For each sensitivity run, the change in the metric can we

⁵⁰⁹ Available at http://www.whitehouse.gov/omb/circulars_a004_a-4/.

described as the difference between the baseline and the preferred alternative for the sensitivity case, minus the

difference between the preferred alternative and the baseline in the main analysis, divided by the difference

between the preferred alternative and the baseline in the main analysis. Or,

$$Table\ Metric = \frac{\Delta_{Alt\ sen\ case} - \Delta_{Alt\ main\ run}}{\Delta_{Alt\ main\ run}} \cdot 100$$

Each metric represents the sum of the impacts of the preferred alternative over the model years 2015–2029, and the

percent changes in the table represent percent changes to those sums. More detailed results for all alternatives are

available in the accompanying RIA Chapter 10.

TABLE VI–23—SENSITIVITY ANALYSIS RESULTS FROM CAFE MODEL IN THE HD PICKUP AND VAN MARKET SEGMENT USING METHOD A AND VERSUS THE DYNAMIC BASELINE, ALTERNATIVE 1b

[2.5% growth in stringency: Cells are percent change from base case]^a

Note:

^a For an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the less dynamic baseline, 1a, and more dynamic baseline, 1b, please see Section X.A.1.

For some of the cases for which results are presented above, the sensitivity of results to changes in inputs is simple, direct, and easily observed. For example, changes to valuation of avoided GHG emissions impact only this portion of the estimated economic benefits; manufacturers' responses and corresponding costs are not impacted. Similarly, a higher discount rate does not affect physical quantities saved (gallons of fuel and metric tons of CO₂ in the table), but reduces the value of the costs and benefits attributable to these standards in an intuitive way. Higher rebound results in fewer volumetric fuel savings and social net benefits, as drivers are assumed to be more responsive in their driving habits

to changes in the cost per mile of travel. Some other cases warrant closer consideration:

First, cases involving alternatives to the reference case involving voluntary over compliance of technologies that pay back in six-months involve different degrees of fuel consumption improvement. Increasing the length of the payback period assumption for voluntary over compliance amounts to increasing fuel economy improvements in the absence of the rule (the baseline), and manufacturers are compelled to add less technology in order to comply with the standards (in the regulatory alternatives). Because all estimated impacts of these standards are shown as incremental values relative to this baseline, longer voluntary over

compliance payback periods correspond to smaller estimates of incremental impacts.

Table VI–24 shows the effect of varying the voluntary over compliance assumption from the consumer perspective. The baseline over-compliance payback period is as described above—the number of months within which a technology must pay back to the consumer in the form of undiscounted retail fuel savings for a manufacturer to voluntarily apply that technology without regulatory action. The incremental per-vehicle technology cost is the average additional cost of technology applied to MY 2030 vehicles under the final regulation (incremental to the baseline) of each sensitivity case. The per-vehicle lifetime fuel savings is

the average lifetime retail value of fuel savings under each sensitivity case discounted at 7 percent annually starting at the time of purchase (MY 2030). Compliance payback period is the number of months of ownership it would take the average consumer to recoup the additional technology costs in discounted fuel savings.⁵¹⁰

As can be seen, the baseline voluntary over compliance assumption changes how much of the technology costs and fuel savings are attributed to the regulation; both fewer fuel savings and fewer technology costs are attributed to the regulatory alternative as the payback period defining voluntary over compliance increases. Further, because the model only applies the technologies

with the shortest payback periods (the most cost-effective technologies) in the baseline, the fuel savings decrease at a greater proportion than the technology costs. The result is that the payback period of the regulatory alternative increases (and at an increasing rate) as manufacturers are assumed to apply more technology in the baseline.

TABLE VI-24—SENSITIVITY ANALYSIS OF THE VOLUNTARY OVER COMPLIANCE ASSUMPTION ON COMPLIANCE PAYBACK PERIOD AND KEY CONSUMER IMPACTS FOR THE MY 2030 MDHD FLEET

Baseline over-compliance payback (months)	Incremental per-vehicle technology cost	Per-vehicle lifetime fuel savings	Technology cost payback period (months) ^a
0	\$1,471	\$3,966	28
6	1,472	3,636	31
12	1,317	3,031	33
18	1,214	2,556	38
24	944	1,684	45

Note:

^a Here the payback calculation uses a 7% discount rate of retail fuel savings starting at the time of purchase and only considers the additional costs of technology application.

Cases involving different fuel prices similarly involve different degrees of fuel economy improvement in the absence of the standard, as more, or less, improvement occurs as a result of more, or fewer, technologies appearing cost effective to owner/operators. Low fuel prices change the amount of fuel savings for each technology, since the choice in technology application also involves both the size of the cost and the fuel savings, lower fuel prices can change the rank of the technologies. Under low fuel prices, the model applies fewer SHEV-P2's. The result is a reduction in volumetric fuel savings, and an even larger reduction in monetary fuel savings, because the fuel savings are worth less. There is also a reduction in social costs, and social net benefits. Higher fuel prices correspond to reductions in the volumetric fuel savings attributable to these standards as, but lead to increases in the value of fuel saved (and net social benefits) because each gallon saved is worth more when fuel prices are high.

The low price and 0-month payback case leads to a significant increase in volumetric savings compared to the main analysis. Note that the fuel savings are higher than in the 0-month payback case alone. Part of the reason for this is that the lower fuel price case takes into consideration that when fuel prices are lower, consumers buy more heavy-duty vehicles (this is estimated from the

AEO2015 low fuel price case). Another piece of the explanation is that the lower fuel prices result in a different technology cost-effectiveness ranking of technologies, and that the 0 month payback baseline results in no voluntary over compliance in the baseline. Different technologies are picked than in the 0 month pay back sensitivity alone, and the most cost effective that would have been applied in the baseline, are now attributed to the preferred alternative. Similarly, the high price and 24-month payback case results in large reductions to volumetric savings that can be attributed to these standards because more is applied in the baseline. Further, the presence of high fuel prices is not sufficient to lead to increases in either the dollar value of fuel savings or net social benefits.

The case which involves the VIUS-based VMT schedules (the high VMT case) results in greater volumetric fuel and GHG-savings attributable to the standards. Under this case the higher estimate of VMT results in more fuel consumption in the baseline, and a higher absolute change in fuel consumption when fuel-saving technologies are applied in the preferred alternative. These higher amount of gallons saved, results in more monetary fuel savings, comparable social costs, and an increase in overall net social benefits attributed to the standards. The low-VMT schedule, developed as an

alternative to the adopted VMT-schedule from the IHS/Polk odometer readings, results in lower volumetric fuel consumption and GHG reductions under the preferred alternative. Lower VMT estimates result in less fuel consumption in the baseline, and a lower absolute change in fuel consumption under the preferred alternative. This schedule attributes lower costs to the standards—the lower fuel savings under the low-VMT schedule changes the technology application decisions of the model, since fewer fuel savings are considered in measure the cost-effectiveness of technologies. The result is lower absolute technology costs, but also lower social net benefits.

The case which makes SHEV-P2's unavailable involves relatively small increases to volumetric fuel savings and CO₂ reductions—not surprising, since SHEV-P2's play only a minor role in the compliance strategy of the preferred alternative in the Method A central analysis. These small increases in fuel savings are associated with small increases in social benefits, slightly larger proportional increases in social costs, but still result in a small increase in social net benefit.

The case that uses the ICM mark-up methodology rather than the RPE methodology results in a reduction of volumetric fuel savings and GHG reductions. The reduction in fuel

⁵¹⁰ This is based on the VMT schedules of average miles driven by age of MDHD pickups and vans and AEO fuel price projections.

savings is accompanied by a reduction in monetary fuel savings, social benefits, social costs, and social net benefits. This is likely due to shifts in technology applications due to different costs mark-

ups associated with different types of technologies under the ICM mark-up methodology.

If, instead of using the values in the main analysis, each sensitivity case

were itself the main analysis, the costs and benefits attributable to the final rule will be as they appear in Table VI–25, below.

TABLE VI–25—COSTS AND BENEFITS OF STANDARDS FOR MY 2015–2029 HD PICKUPS AND VANS UNDER ALTERNATIVE ASSUMPTIONS

Sensitivity case	Fuel savings (billion gallons)	CO ₂ reduction (MMT)	Fuel savings (\$billion)	Social costs (\$billion)	Social benefits (\$billion)	Net social benefits (\$billion)

(9) Discussion of the Maximum Feasibility of the Adopted Standards

As noted above, EPCA and EISA require NHTSA to “implement a commercial medium- and heavy-duty on-highway vehicle and work truck fuel efficiency improvement program designed to achieve the maximum feasible improvement” and to establish corresponding fuel consumption standards “that are appropriate, cost-effective, and technologically feasible.”⁵¹¹ In order to determine which of the regulatory alternatives meets the requirements of the statute NHTSA has considered both the modeling results of “Method A” and comments offered on the proposed rulemaking.

(a) Consideration of Modeling Results

For both the NPRM and the current analysis of potential standards for HD pickups and vans, NHTSA applied NHTSA’s CAFE Compliance and Effects Modeling System (sometimes referred to as “the CAFE model” or “the Volpe model”), which DOT’s Volpe National Transportation Systems Center (Volpe

Center) developed, maintains, and applies to support NHTSA CAFE analyses and rulemakings. NHTSA used this model in its Method A analysis to evaluate regulatory alternatives for Phase 2 standards applicable to HD pickups and vans, and used results of this analysis to inform its selection of the regulatory alternative that will achieve the maximum feasible improvement in HD pickup and van fuel efficiency. This analysis includes several updates to the model and to accompanying inputs, as discussed above in this section.

In the proposal, the agencies proposed to adopt Alternative 3 from among the five regulatory alternatives under consideration.⁵¹² As discussed in the NPRM, the agencies found that Alternative 2 would unduly forego significant fuel savings and avoided GHG emissions, and that Alternative 5 could involve rapid and early cost increases and necessitate significant application of the most advanced technologies considered by the agencies. 80 FR 40494–40495. The agencies have estimated the cost and efficacy of fuel-

saving technologies assuming performance and utility will be held constant or improved. In particular, we have assumed payload will be preserved (and possibly improved via reduced vehicle curb weight); however, some fuel-saving technologies, such as hybrid electric vehicles, could reduce payload via increased curb weight (due to the added electrical machine, batteries and controls, and because of the physical size of those components). If the increase in weight from the hybrid system is not offset with a weight reduction elsewhere in the vehicle, the payload capability will be reduced resulting in lost utility but also an increase in stringency due to changes in work factor. Further, it is also possible that applications such as vans where the advanced technologies of downsized gasoline and diesel engines could be used in conjunction with strong hybridization, extended high power demand resulting from a vehicle at full payload or towing, certain types of hybrid powertrains could experience a temporary loss of towing capacity if the capacity of the hybrid’s energy storage device (e.g., batteries, hydraulic accumulator) is insufficient for the

⁵¹¹ 49 U.S.C. 32902(k)(2).

⁵¹² These Alternatives are defined in Section C(6).

extended power demand required to maintain expected vehicle speeds.

The Method A analysis shows in the short term, MY 2017–2021 timeframe, that there are significant differences in the rate at which technologies would need to be applied among the alternatives. NHTSA believes the rates of technology application require for Alternatives 4 and 5 are beyond

maximum feasible when considering the availability of manufacturers' resources and capital to implement the technologies in that timeframe, and that Alternatives 4 and 5 would not provide adequate lead time for the industry to fully address reliability considerations.

Like the NPRM analysis (*i.e.* the Method B analysis), Method A indicates Alternative 4 would achieve little benefit

beyond that achieved by Alternative 3. For example, as shown in the following graph of estimated total fuel consumed by HD pickups and vans over time under the various regulatory alternatives, outcomes under Alternative 4 are nearly indistinguishable from those under Alternative 3. By 2030, the two are less than 0.5 percent apart.

Figure VI-30 Method A Annual Fuel Consumption across Regulatory Alternatives

Weighing against the small additional benefit estimated to be potentially available under Alternative 4, NHTSA also considered the estimated additional costs. Method A analysis shows overall incremental costs (*i.e.*, costs beyond the No Action Alternative) under Alternative 4 to be about 12 percent more than under Alternative 3.

As mentioned above, these estimated differences were mostly small on a relative basis. Averaged over all model years included in the analysis, estimated incremental costs are \$106 higher under Alternative 4 than under Alternative 3. For Daimler and General Motors, there is little or no estimated difference in costs under these two Alternatives. For FCA, Ford, and Nissan, differences are somewhat larger, averaging \$120, \$173, and \$272,

respectively. However, as explained in greater detail above, NHTSA's method A analysis shows considerably greater total and average additional costs in earlier model years under Alternative 4 than under Alternative 3.

Although NHTSA's Method A analysis also indicates that some manufacturers could need to apply additional technology as soon as MY 2016 under baseline standards defining the No-Action Alternative, average estimated costs (versus continuation today's technology) in MY 2017 are two thirds more under Alternative 4 than under the No Action Alternative.

Beyond these directly-estimated costs, the agencies also considered factors beyond those addressed quantitatively in either the NPRM analysis or the updated analysis. In general, these other

factors reflect risk and uncertainty involved with standards for HD pickups and vans. These risks and uncertainty appear considerably greater than for light-duty vehicles. The HD pickup and van market has significantly fewer vehicle models than the light-duty market making forecasting uncertainty a greater risk to compliance. All current manufacturers of HD pickups and vans also produce light-duty vehicles. These manufacturers' light-duty offerings span wide ranges of models, configurations, shared vehicle platforms, engines, transmissions, and design schedules. As a result, if some specific aspects of production do not progress as initially planned for light-duty vehicles (*e.g.*, if mass reduction on some platform does not achieve as much benefit as planned, or if a new engine does not perform as

well as projected, or if limited engineering resources make it necessary to delay a redesign), these manufacturers should have ample opportunity to comply with light-duty CAFE and GHG standards by making

adjustments among other models, platforms, engines, and transmissions. This is not the case for HD pickups and vans. Current HD PUV manufacturers offer products spanning only 1–3 platforms, at most half a dozen engines

or transmissions, and only 1–3 schedules for redesigns. As summarized below, this provides 5–10 times less flexibility than for light-duty vehicles.

TABLE VI–26—MY 2015 BODY AND ENGINE PLATFORMS BY MANUFACTURER FOR LIGHT- AND HEAVY-DUTY PICKUPS

	Platforms		Engines		Transmissions		Design Schedules	
	Light-duty	HD PUV	Light-duty	HD PUV	Light-duty	HD PUV	Light-duty	HD PUV
Daimler	12	1	29	2	20	2	18	1
FCA	15	3	24	5	21	6	24	3
Ford	9	2	22	5	27	3	18	2
General Motors	17	2	26	5	39	3	21	2
Nissan	6	1	13	2	21	2	23	1

Considering further that credits from other manufacturers are not potentially available as for light-duty vehicles (e.g., several manufacturers currently have excess light-duty CAFE credits that could be traded to other OEMs), this means that overestimating the industry's capability to improve fuel efficiency and reduce GHG emissions, and consequently setting standards at too stringent of a level, poses a much greater compliance risk for HD PUV fleets than for light-duty fleets. If the factors discussed here, for which the agencies are currently unable to account in our analysis, lead manufacturers to fail to comply with the standards, then the additional benefits of setting standards at slightly more stringent levels would be lost. In the agencies' judgment, even setting aside the somewhat higher estimated costs under Alternative 4, the very small additional benefit that could be achieved under Alternative 4 do not warrant the increased exposure to this risk.

Regarding Alternative 5, the Method A analysis shows somewhat greater benefits than under Alternatives 3 or 4, but Alternative 5 entails considerably greater costs and dependence on strong hybrid technology, as well as even greater exposure to the above-mentioned uncertainties and risks. Under the Method A analysis for Alternative 5, incremental costs averaged across all model years considered are estimated to be about \$400 higher (about 46 percent) than under Alternative 3, and that analysis shows an overall fleet application of approximately 7 percent strong hybrids, with General Motors applying approximately 13 percent and Ford approximately 7 percent.

We have also assumed that fuel-saving technologies will be no more or less reliable than technologies already in production. However, if there is insufficient lead-time to fully develop

new technologies, they could prove to be less reliable, perhaps leading to increased repair costs and out-of-service time. If the fuel-saving technologies considered here ultimately involve reliability problems, overall costs will be greater than we have estimated. Method A analysis shows in the short term, MYs 2017–2021 timeframe, there are significant differences in the rate at which technologies would need to be applied among the alternatives. Figures VI.15 and VI.16, above, shows the progression in average and total technology costs and the rate of increase in those costs among the alternatives using Method A. They highlight the increases in resources and capital that would be required to implement the technologies required to comply with each of the alternatives, as well as the reduction in lead time to implement the technologies which increases reliability risk. As discussed further above in the manufacturer-specific effects, Ford and FCA are estimated to redesign vehicles in MYs 2017 and 2018 respectively, and vehicle designs for those model years are complete or nearly complete. The next estimated redesign for Ford is in MY 2026, and for FCA in MY 2025, and substantial resources and very high costs would be required to add another vehicle redesign between the estimated redesign model years to implement the technologies that would be needed to comply with those alternatives.

(b) Consideration of Comments

NHTSA proposed that Alternative 3 represented the maximum feasible alternative under EISA, and EPA proposed that Alternative 3 reflected a reasonable consideration of the statutory factors of technology effectiveness, feasibility, cost, lead time, and safety for purposes of CAA sections 202(a)(1) and (2). Although the agencies and commenters also found that Alternative

4 merited serious consideration, the agencies noted that Alternative 3 was generally designed to achieve the levels of fuel consumption and GHG stringency that Alternative 4 would achieve, but with several years of additional lead time, meaning that manufacturers could, in theory, apply new technology at a more gradual pace, with greater reliability and flexibility.

Some comments on the proposal called for adoption of standards more stringent and/or more rapidly advancing in stringency than those defining Alternative 3. For example, CARB argued that Alternative 4 would, compared to Alternative 3, achieve greater benefits comparably attractive in terms of cost effectiveness and while remaining less stringent than CAFE standards for light-duty trucks.⁵¹³ UCS provided similar comments, indicating further that the standards should be technology forcing and therefore more aggressive than Alternative 4, they specifically suggested that gasoline vehicles could achieve up to a 23.6 percent improvement in MY 2027 while diesel vehicles can achieve an 18 percent improvement.⁵¹⁴ ACEEE similarly recommended increasing the stringency by 7 percent in MY 2027 and that standards should reflect increased use of cylinder deactivation, cooled EGR, and GDI and turbo downsizing in pickups. For diesels, ACEEE commented that additional reductions were possible, based on an estimate of 10 percent penetration of engine downsizing for pickups and 30 percent penetration for vans in 2027, and also assuming 6 percent penetration of hybrids in diesel vans.

Citing the potential for fuel-saving technology to migrate from light-duty

⁵¹³ CARB, Docket No. NHTSA–2014–0132–0125 at pages 52–53.

⁵¹⁴ UCS, Docket No. EPA–HQ–OAR–2014–0827–1329, at pages 23–25.

pickups and vans to heavy-duty pickups and vans, CBD also called for more stringent HD pickup and van standards that would “close the gap” with light-duty standards, as any gap allows manufacturers to essentially choose to classify a pickup as heavy-duty to avoid more stringent requirements if it was classified as a light-duty vehicle.⁵¹⁵ ICCT likewise commented that the proposed standards represent only a 2.2 and 1.6 percent year-over-year improvement for the gasoline and diesel fleets, respectively, from MYs 2014–2025 compared to an almost 3 percent per year improvement for light-duty trucks in the same time frame. ICCT recommended that the agencies’ analysis incorporate the full analysis and inputs from the light-duty rulemaking and that the result would be improvements in the range of 35 percent over the MYs 2014–2025 rather than the proposed 23 percent improvement over this time frame.

On the other hand, some other reviewers commented that the proposed standards could be unduly aggressive considering the products and technologies involved. GM commented that any attempt to force more stringent regulations than proposed, such as Alternative 4, would be extremely detrimental to manufacturers, consumers, the U.S. economy, and the millions of transportation-related jobs. Daimler similarly commented that the proposed standards would be a challenge for automotive manufacturers. Under certain conditions, such a standard may necessitate hybridization of the affected vehicle fleet, which would require substantial development and material costs. All technologies taken into account for the class 2b/3 stringencies should reflect cost effectiveness calculations, especially alternative powertrains such as hybrids, battery, and fuel cell driven electric vehicles. Daimler recommends that the agencies adopt the proposed standard over Alternative 4, as the additional two years of lead-time will be critical for automotive manufacturers in developing the necessary technologies to achieve compliance. Nissan commented that the Alternative 4 3.5 percent per stringency level is simply not feasible, as it does not provide the necessary lead-time to enable manufacturers to balance competitive market constraints with the cost of applying new technologies to a limited product offering. Nissan further commented that to the extent that the more stringent alternative is predicated on the adoption of hybrid and electric

powertrain technology, Nissan does not believe that such technology is feasible for this market segment.

The American Automotive Policy Council (AAPC, representing FCA, Ford, and General Motors) further commented that proposals for greater stringency than Alternative 3 are not supportable given the required early introduction of unproven technologies with their associated consumer acceptance risk, as well as the many implicit risks that impact stringency. AAPC commented that the proposed standards are aggressive and will challenge industry. AAPC noted that the baseline fleet includes a high percentage of advanced diesel technology such as SCR, making additional improvements considerably more challenging. In the light-duty fleet, diesel technology accounts for 3 percent of fleet whereas the heavy-duty fleet consists of over 50 percent diesel.

AAPC also noted that Phase 2 technologies are being used today. For example, FCA’s modern gasoline engine has robust combustion with multiple spark plugs, variable cam phasing, cylinder deactivation, and cooled EGR. AAPC commented that even with this level of gasoline engine technology, FCA is challenged by the early year Phase 1 standards and will need to look at adding even more technology for Phase 2. AAPC also provided data showing that while smaller displacement boosted gasoline engine technology may be applicable in some variants of commercial vans, this technology is not suited for the pickup truck variants in this segment because of customer demands for towing capability. AAPC commented that concurrent stringency increases in Tier 3/LEV III criteria emission requirements will negatively impact CO₂ and fuel consumption. As an alternative to the standards proposed in the NPRM, the American Automotive Policy Council (AAPC, representing FCA, Ford, and General Motors) proposed standards that would achieve the stringency by model year 2027, but that would do so at a more gradual pace.⁵¹⁶ As means of providing flexibility in complying with these standards, AAPC also commented that the agencies should allow credits to be banked for longer than 5 years, and should allow credits to be transferred between the light- and heavy-duty fleets.⁵¹⁷

⁵¹⁶ AAPC, Docket No. NHTSA–2014–0132–0103], at pages 12–13.

⁵¹⁷ AAPC, Docket No. NHTSA–2014–0132–0103 at pages 13–16.

(c) Determination

Having considered these comments as well as the updated analysis summarized above, NHTSA is adopting standards under which the stringency of fuel consumption standards for HD pickups and vans advance at an annual rate of 2.5 percent during model years 2021–2027 relative to the 2018 MY Phase 1 standard level. In NHTSA’s judgment, this pace of stringency increase will appropriately accommodate manufacturers’ redesign workload and product schedules, especially in light of this sector’s limited product offerings⁵¹⁸ and long product cycles. Given the provided flexibility to carry credits forward (and back) between model years, this approach strikes a balance between, on one hand, meaningful early fuel efficiency improvements and, on the other, providing manufacturers appropriate lead time.

Compared to Alternative 3, Alternative 2 would forego significant cost-efficient opportunities to apply conventional and moderately advanced technology in order to reduce fuel consumption and emissions. Also, although the updated analysis summarized above shows costs for Alternative 3 (as costs incremental to the No Action Alternative) somewhat higher than estimated in the NPRM analysis, the agencies find that under either the Method A or Method B analyses, AAPC’s proposed more gradual progression leading up to MY 2027 would also forego cost-effective improvements which are readily feasible in the lead time provided. Furthermore, the Method A analysis indicates that the standards defining Alternative 3 can likely be met with minimal reliance on hybrid technologies. Considering this, NHTSA also find it unnecessary to extend the lifespan of banked credits or adopt other credit related flexibilities to mitigate the stringency increases under Alternative 3.

E. Analysis of the Regulatory Alternatives for HD Pickups and Vans: Method B

Section 202(a)(1) and (2) of the Clean Air Act require EPA to establish standards for emissions of pollutants from new motor vehicles and engines which emissions cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare, which include GHGs. See Section I.E. above. Under section 202(a)(1) and (2), EPA considers such

⁵¹⁸ Manufacturers generally have only one pickup platform and one van platform in this segment.

⁵¹⁵ CBD, Docket No. NHTSA–2014–0132–0101, at pages 8–9.

issues as technology effectiveness, its cost (both per vehicle, per manufacturer, and per consumer), the lead time necessary to implement the technology, and based on this the feasibility and practicability of potential standards; the impacts of potential standards on emissions reductions of both GHGs and non-GHG emissions; the impacts of standards on oil conservation and energy security; the impacts of standards on fuel savings by customers; the impacts of standards on the truck industry; other energy impacts; as well as other relevant factors such as impacts on safety.

As part of the proposed feasibility analysis of potential standards for HD pickups and vans, the agencies applied NHTSA's CAFE Model. The agencies used this model to identify technology pathways that could be used to meet a range of stringencies, based on our projections of technology that will be available in the Phase 2 time frame. The agencies considered these technology pathways and identified the stringency level that will be technology-forcing (*i.e.* reflect levels of stringency based on performance of emerging as well as currently available control technologies) at reasonable cost, and leave manufacturers the flexibility to adopt varying technology paths for compliance and allow adequate lead time to develop, test, and deploy the range of technologies.

As noted in Section I and discussed further below, the analyses consider two versions of the CAFE model, one updated for the NPRM analysis represented here in Method B, and one further updated for the FRM represented in the Method A analysis described in D immediately preceding this section. The results of both versions are reported relative to two baselines, a flat baseline (designated Alternative 1a) where no improvements are modeled beyond those needed to meet Phase 1 standards and a dynamic baseline (designated Alternative 1b) where certain cost-effective technologies (*i.e.*, those that payback within a 6 month period) are assumed to be applied by manufacturers to improve fuel efficiency beyond the Phase 1 requirements in the absence of new Phase 2 standards. NHTSA considered its primary analysis to be based on the more dynamic baseline of Method A, whereas EPA considered the flat baseline of Method B. As shown below and in Sections VII through X, using the two different reference cases has little impact on the results of the analysis and leads to the same conclusion regarding the appropriateness of the Phase 2 standards. As such, the use of different

reference cases corroborates the results of the overall analysis.

For the NPRM, the agencies conducted coordinated and complementary analyses by employing both NHTSA's CAFE model and EPA's MOVES model and other analytical tools to project fuel consumption and GHG emissions impacts resulting from the Phase 2 standards for HD pickups and vans, against both the flat and dynamic baselines. EPA ran its MOVES model for all HD categories, namely tractors and trailers, vocational vehicles and HD pickups and vans, to develop a consistent set of fuel consumption and CO₂ reductions for all HD categories. The MOVES runs followed largely the procedures described above, with some differences. MOVES used the same technology application rates and costs that are part of the inputs, and used cost per vehicle outputs of the CAFE model to evaluate the Phase 2 standards for HD pickup trucks and vans. The agencies note that these two independent analyses of aggregate costs and benefits both support these standards. For the final rule, NHTSA has conducted an analysis using a revised version of the CAFE model, as discussed in Section D. This analysis has been designated Method A. The EPA analysis based on the NPRM version of the CAFE model along with EPA's MOVES model is designated Method B.

As noted earlier, the agencies are adopting as proposed a phase-in schedule of reduction of 2.5 percent per year in fuel consumption and CO₂ levels relative to the 2018 MY Phase 1 standard level, starting in MY 2021 and extending through MY 2027. We continue to believe this phased-in implementation will appropriately accommodate manufacturers' redesign workload and product schedules, especially in light of this sector's limited product offerings⁵¹⁹ and long product cycles. This approach was chosen to strike a balance between meaningful reductions in the early years and providing manufacturers with needed lead time via a gradually accelerating ramp-up of technology penetration. By expressing the phase-in in terms of increasing year to year stringency for each manufacturer, while also providing for credit generation and use (including averaging, carry-forward, and carry-back), we believe our program will afford manufacturers substantial flexibility to satisfy the phase-in through a variety of pathways: The gradual application of technologies across the fleet, greater application

levels on only a portion of the fleet, and a sufficiently broad set of available technologies to account for the variety of current technology deployment among manufacturers and the lowest-cost compliance paths available to each.

EPA did not estimate the cost of implementing these standards immediately in 2021 without a phase-in, but we qualitatively assessed it to be somewhat higher than the cost of the phase-in we are establishing, due to the workload and product cycle disruptions it could cause, and also due to manufacturers' resulting need to develop some of these technologies for heavy-duty applications sooner than or simultaneously with light-duty development efforts. See 75 FR 25451 (May 7, 2010) (documenting types of drastic cost increases associated with trying to accelerate redesign schedules and concluding that "[w]e believe that it would be an inefficient use of societal resources to incur such costs when they can be obtained much more cost effectively just one year later"). On the other hand, waiting until 2027 before applying any new standards could miss the opportunity to achieve meaningful and cost-effective early reductions not requiring a major product redesign. Comments on the phase-in are discussed in Section B.2. and in the Response to Comments document.

As noted above, at proposal, the agencies requested comment in particular on Alternative 4. EPA is not adopting Alternative 4 due to uncertainty regarding whether or not the potential technologies and market penetration rates included in Alternative 4 would be technologically feasible. Alternative 4 would ultimately reach the same levels of stringency as final Phase 2 standards, but would do so with less lead time. As discussed below, this could require application of both different technologies at higher application rates, neither of which may be feasible (or, at the least, reliable implementable) by MY 2025.

Moreover, the two years of additional lead time provided by the final standards compared to Alternative 4 eases compliance burden by having more vehicle redesigns and lower stringency during the phase-in period. As noted above, historically, the vehicles in this segment are typically only redesigned every 6–10 years, so many of the vehicles may not even be redesigned during the timeframe of the stringency increase. In this case, a manufacturer must either make up for any vehicle that falls short of its target through some combination of early compliance, over compliance, credit carry-forward and carry-back, and

⁵¹⁹ Manufacturers generally have only one pickup platform and one van platform in this segment.

redesigning vehicles more frequently. Each of these will increase technology costs to the manufacturers and vehicle purchasers, and early redesigns will significantly increase capital costs and product development costs. Also, the longer implementation time for the final standards means that any manufacturer will have a slightly lower target to meet from 2021–2026 than for the shorter phase-in of Alternative 4, though by 2027 the manufacturers will have the same target in either alternative.

Due to the projected higher technology adoption rates, Alternative 4 is also projected to result in higher costs, and risks of inadequate time to successfully test and integrate new technology, than the standards the agencies are adopting. Moreover, the additional emission reductions and fuel savings predominately occur only during the program phase-in period; from roughly 2030 on, the adopted standards and the pull-ahead alternative are projected to be equivalent from an environmental benefit standpoint. EPA's analysis and responses to comments are discussed in detail below.

In some cases, the Method B (NPRM) version of the model selects strong hybrids as a more cost effective technology over certain other technologies including stop-start and mild hybrid. In other words, strong hybrids are not a technology of last resort in the analysis. Alternative 4 is projected to be met using a significantly higher degree of hybridization including the use of more strong hybrids, compared to the standards the agencies are finalizing. In order to comply with a 3.5 percent per year increase in stringency over MYs 2021–2025, Method B modeling projects that manufacturers would need to adopt more technology compared to the 2.5 percent per year increase in stringency over MYs 2021–2027. The two years of additional lead time provided by the Phase 2 standards reduces the potential number of strong hybrids projected to be used by allowing for other more cost effective technologies to be more fully utilized across the fleet. EPA believes it is technologically feasible to apply this projected amount of hybridization to HD pickups and vans in the lead time provided (*i.e.*, by MY 2027). However, strong hybrids present challenges in this market segment compared to light-duty where there are several strong hybrids already available. EPA does not believe that at this stage there is enough

information about the viability of strong hybrid technology in this vehicle segment to assume that they can be a part of large-volume deployment strategies for regulated manufacturers. For example, EPA believes that hybrid electric technology could provide significant GHG and fuel consumption benefits, but recognize that there is uncertainty at this time over the real world effectiveness of these systems in HD pickups and vans, and over customer acceptance of the technology for vehicles with high GCWR towing large loads. Further, the development, design, and tooling effort needed to apply this technology to a vehicle model is quite large, and might not be cost-effective due to the small sales volumes relative to the light-duty sector.

Additionally, EPA recognizes that sufficient engine horsepower and torque needed to meet towing objectives which are important to pickup truck buyers and accordingly the analysis does not down-size engines in conjunction with hybridization. See Section VI.C.4.iv above. Therefore, with no change projected for engine size, the strong hybrid costs do not include costs for engine changes. In light-duty, the use of smaller engines has an associated cost saving which facilitates much of a hybrid's cost-effectiveness. Section E.2 discusses these issues further, and explains further that the results of the updated CAFE model used in Method A are consistent with these conclusions.

Due to these considerations in the NPRM and in the current Method B analysis, EPA has conducted a sensitivity analysis using the Method B version of the model that assumes the use of no strong hybrids. The results of the analysis are also discussed below. The analysis indicates that there will be a technology pathway that will allow manufacturers to meet the final standards without the use of strong hybrids. However, the analysis indicates that costs will be higher and the cost effectiveness will be lower under the no strong hybrid approach.

EPA also analyzed less stringent standards under which manufacturers could comply by deploying a more limited set of technologies than are needed to meet the Phase 2 standards being adopted. However, our assessment concluded with a high degree of confidence that the technologies on which the final Phase 2 standards are premised will be available at reasonable cost in the 2021–2027 timeframe, and

that the phase-in and other flexibility provisions allow for their application in a very cost-effective manner, as discussed in this section below. Accordingly, it would be inappropriate (within the meaning of CAA section 202(a)(1) and (2)) to adopt standards of lesser stringency.

More difficult to characterize is the degree to which more or less stringent standards might be appropriate because of under- or over-estimating the costs or effectiveness of the technologies whose performance is the basis of the Phase 2 standards. For the most part, these technologies have not yet been applied to HD pickups and vans, even on a limited basis. EPA is therefore relying to some degree on engineering judgment in predicting their effectiveness. Even so, we believe that we have applied this judgment using the best information available, primarily from a NHTSA contracted study at SwRI⁵²⁰ and our recent rulemaking on light-duty vehicle GHGs and fuel economy, and have generated a robust set of effectiveness values. Chapter 10 of the RIA provides a detailed description of the CAFE Model and the analysis performed for the rule.

(1) Consistency of the Phase 2 Standards With the EPA's Legal Authority

Table VI–27 below shows projected technology adoption rates for both the final Phase 2 standards and for a two-year pull ahead of those standards (*i.e.* Alternative 4 from the NPRM). As at proposal, the table shows that the Method B (EPA's central estimate) analysis estimates that the most cost-effective way to meet the final Phase 2 standards will be to use strong hybrids in up to 9.9 percent of pickups and 5.5 percent of vans on an industry-wide basis. The analysis of Alternative 4 shows strong hybrids on up to 19 percent of pickups (and two years sooner). The analysis shows that the two years of additional lead time provided by the Phase 2 standards compared to Alternative 4 will provide manufacturers with a better opportunity to maximize the use of technologies which are more cost effective than strong hybrids over time thereby reducing the need for strong hybrids which may be particularly challenging for this market segment, as well as providing needed time for the more limited deployment of this technology projected under alternative 3 (*i.e.* the Phase 2 standard).

Technology Study—Report #1. (Report No. DOT HS

812 146). Washington, DC: National Highway Traffic Safety Administration.

TABLE VI-27—METHOD B CAFE MODEL TECHNOLOGY ADOPTION RATES FOR THE FINAL PHASE 2 STANDARDS RULE AND ALTERNATIVE 4 SUMMARY—FLAT BASELINE

Technology	Phase 2 standards (2.5% per year) 2021 to 2027		Alternative 4 (3.5% per year) 2021 to 2025	
	Pickup trucks %	Vans %	Pickup trucks %	Vans %
Low friction lubricants	100	100	100	100
Engine friction reduction	100	100	100	100
Cylinder deactivation	22	19	22	19
Variable valve timing	22	82	22	82
Gasoline direct injection	0	63	0	80
Diesel engine improvements	60	3.6	60	3.6
Turbo downsized engine	0	63	0	63
8 speed transmission	98	92	98	92
Low rolling resistance tires	100	92	100	59
Aerodynamic drag reduction	100	100	100	100
Mass reduction and materials	100	100	100	100
Electric power steering	100	49	100	46
Improved accessories	100	87	100	36
Low drag brakes	100	45	100	45
Stop/start engine systems	0	0	15	1.5
Mild hybrid	0	0	29	15
Strong hybrid	9.9	5.5	19	0

As discussed earlier, EPA also conducted a sensitivity analysis using the Method B version of the model to determine a compliance pathway where no strong hybrids would be utilized. Although EPA in this Method B analysis, projects that strong hybrids may be the most cost effective approach, manufacturers may select another compliance path, mainly a 20 percent penetration rate of mild hybrids. This no strong hybrid analysis included the use of downsized turbocharged engines in vans currently equipped with large V-8 engines. Turbo-downsized engines were not allowed on 6+ liter gasoline vans in the primary analysis because EPA sought to preserve consumer choice with respect to vans that have

large V-8s for towing. However, given the recent introduction of vans with considerable towing capacity and turbo-downsized engines, EPA believes it will be feasible for vans in the time-frame of these final rules. The tables below reflect the difference in predicted penetration rates of technologies if strong hybridization is not chosen as a technology pathway. For simplicity, pickup trucks and vans are combined into a single industry wide penetration rate.

The table also shows that when strong hybrids are used as a pathway to compliance, penetration rates of all hybrid technologies would increase substantially between the Phase 2 standards and Alternative 4. The

analysis predicts an increase in strong hybrid penetration from 8 percent to 12 percent, a 23 percent penetration of mild hybrids and a 10 percent penetration stop/start engine systems for Alternative 4 compared with the Phase 2 standards (hence much of the increased projected cost between these options, as explained below). Also, by having the final standards apply in MY 2027 instead of MY 2025, the rule is not premised on use of any mild hybrids or stop/start engine systems. This analysis shows that the few years of additional lead time provided by the Phase 2 standards allows manufacturer's important flexibility in choosing a mix of technologies that is best suited for this market.

TABLE VI-28—CAFE METHOD B MODEL TECHNOLOGY ADOPTION RATES FOR FINAL PHASE 2 STANDARDS AND ALTERNATIVE 4 COMBINED FLEET AND FUELS SUMMARY—FLAT BASELINE

Technology	Phase 2 standards (2.5% per year) 2021 to 2027		Alternative 4 (3.5% per year) 2021 to 2025	
	With strong hybrids %	Without strong hybrids %	With strong hybrids %	Without strong hybrids %
Low friction lubricants	100	100	100	100

TABLE VI-28—CAFE METHOD B MODEL TECHNOLOGY ADOPTION RATES FOR FINAL PHASE 2 STANDARDS AND ALTERNATIVE 4 COMBINED FLEET AND FUELS SUMMARY—FLAT BASELINE—Continued

Technology	Phase 2 standards (2.5% per year) 2021 to 2027		Alternative 4 (3.5% per year) 2021 to 2025	
	With strong hybrids %	Without strong hybrids %	With strong hybrids %	Without strong hybrids %
Low drag brakes	78	93	78	78
Stop/start engine systems	0	1	10	4
Mild hybrid	0	20	23	66
Strong hybrid	8	0	12	0

Note:

^a The 6+ liter V8 vans were allowed to convert to turbocharged and downsized engines in the “without strong hybrid” analysis for both the Rule and the Alternative 4 to provide a compliance path.

The tables Table VI-29 and Table VI-30 below provide a further breakdown of projected technology adoption rates specifically for gasoline-fueled pickups and vans which shows potential adoption rates of strong hybrids for each vehicle type. Strong hybrids are not projected to be used in diesel

applications. The Alternative 4 analysis shows the use of strong hybrids in up to 48 percent of gasoline pickups, depending on the mix of strong and mild hybrids, and stop/start engine systems in 20 percent of gasoline pickups (the largest gasoline HD segment). It is important to again note

that this analysis only shows one pathway to compliance, and the manufacturers may make other decisions, *e.g.*, changing the mix of strong vs. mild hybrids, or applying electrification technologies to HD vans instead.

TABLE VI-29—CAFE METHOD B MODEL TECHNOLOGY ADOPTION RATES FOR FINAL PHASE 2 STANDARDS AND ALTERNATIVE 4 ON GASOLINE PICKUP TRUCKS—FLAT BASELINE

Technology	Phase 2 standards (2.5% per year) 2021 to 2027		Alternative 4 (3.5% per year) 2021 to 2025	
	With strong hybrids %	Without strong hybrids %	With strong hybrids %	Without strong hybrids %

Notes:

^a The 6+ liter V8 vans were allowed to convert to turbocharged and downsized engines in the “without strong hybrid” analysis for both the Rule and the Alternative 4 to provide a compliance path.

^b Depending on extent of strong hybrid adoption as hybrid technologies can replace each other, however they will have different effectiveness and costs.

EPA projects a compliance path for these standards showing aggressive implementation of technologies that the agencies consider to be available in the time frame of these rules. See Section VI.C.4. Under this approach, manufacturers are expected to implement these technologies at aggressive adoption rates on essentially all vehicles across this sector by 2027 model year. In the case of several of these technologies, adoption rates are projected to approach 100 percent. This includes a combination of engine, transmission and vehicle technologies as described in this section across every vehicle. The standard also is premised on less aggressive penetration of particular advanced technologies, including strong hybrid electric vehicles.

EPA projects the Phase 2 standards to be achievable within known design cycles, and we believe these standards will allow different paths to compliance in addition to the one we outline and cost here. As discussed below and throughout this analysis, our rule places a high value on the assurance of in use reliability and market acceptance of new technology, particularly in initial model years of the program.

The NPRM analysis did not predict substantial amounts of technology being added before the start of the MY 2021 standards, and in particular, did not project that there would be substantial additions of more advanced

technologies in any redesign cycles occurring before MY 2021. This continues to appear to be a reasonable assumption, since substantial lead time is typically required to develop and implement these advanced technologies. Indeed, as the previous discussion shows (and as discussed again in responding to comments later in this section), it is important to provide two additional years of lead time between MY 2025 and 2027. More recent modeling used to update the NHTSA Method A analysis as described in Section C above allows for technology implementation in pre-2021 model years to both meet the final Phase 1 standards in MY 2018 and to also begin to introduce advanced technologies that will eventually be needed in order to meet the Phase 2 standards. EPA considered this more recent modeling approach with earlier redesign cycles and technology implementation and agrees with NHTSA that this modelling shows that there would be insufficient lead time to adopt the technologies to satisfy the compliance path modelled for Alternatives 4 and 5 in the Method A analysis. See Section VI.D.4 above.

As discussed above, the agencies sought comment on the feasibility and costs associated with the standards being finalized and also on alternative standards. In particular, the agencies sought comment on Alternative 4, which is based on a year-over-year increase in stringency of 3.5 percent in

MYs 2021–2025, essentially pulling ahead the alternative 3 standard stringency by two model years. The agencies received several comments in support of more stringent standards. Several NGOs commented that more stringent standards than proposed are feasible through the additional application of technology and that the standards should more closely align with standards established for light-duty trucks. UCS commented that gasoline vehicles could achieve up to a 23.6 percent improvement in MY 2027 while diesel vehicles can achieve an 18 percent improvement. ACEEE similarly recommended increasing the stringency by 7 percent in MY 2027 and that standards should reflect increased use of cylinder deactivation, cooled EGR, and GDI and turbo downsizing in pickups. For diesels, ACEEE commented that additional reductions were possible, based on an estimate of 10 percent penetration of engine downsizing for pickups and 30 percent penetration for vans in 2027, and also assuming 6 percent penetration of hybrids in diesel vans. ICCT commented that the proposed standards represent only a 2.2 and 1.6 percent year-over-year improvement for the gasoline and diesel fleets, respectively, from MYs 2014–2025 compared to an almost 3 percent per year improvement for light-duty trucks in the same time frame. ICCT recommended that the agencies’ analysis incorporate the full analysis

and inputs from the light-duty rulemaking and that the result would be improvements in the range of 35 percent over the MYs 2014–2025 rather than the proposed 23 percent improvement over this time frame.

The agencies also received comments that any gap between fuel economy requirements for LD and HD pickups for which there is no engineering rationale could produce distortions in the pickup market, shifting sales toward the heavier vehicles. The Center for Biological Diversity similarly commented that closing the gap between large light-duty and heavy-duty pickups and vans is crucial because the overlap in many characteristics allows manufacturers to essentially choose to classify a pickup as “heavy duty” to avoid the more stringent requirements for “light duty” pickups through minor adjustments to the vehicle.

CARB staff commented in support of Alternative 4, commenting that Alternative 4 is technologically feasible, cost-effective and superior to Alternative 3. CARB noted that the Alternative 4 adds only three to 8 months to the payback period. CARB also commented that Alternative 4 remains significantly less stringent than the light-duty truck standards. CARB further commented that Alternative 4 would result in greater emissions and societal benefits than Alternative 3.

The agencies also received several comments opposing setting standards more stringent than those proposed, although none of these commenters opposed the actual proposal. AAPC commented that proposals for greater stringency than Alternative 3 are not supportable given the required early introduction of unproven technologies with their (purportedly) associated consumer acceptance risk, as well as the many implicit risks that impact stringency. AAPC commented that, in their view, the proposed standards are aggressive and will challenge industry. AAPC noted that the baseline fleet (which is over 50 percent diesel) includes a high percentage of advanced diesel technology such as SCR, making additional improvements more challenging. AAPC also noted that Phase 2 technologies are being used today. For example, FCA’s modern gasoline engine has robust combustion with multiple spark plugs, variable cam phasing, cylinder deactivation, and cooled EGR. AAPC commented that even with this level of gasoline engine technology, FCA is challenged by the early year Phase 1 standards and will need to look at adding even more technology for Phase 2. AAPC also provided data showing that while

smaller displacement boosted gasoline engine technology may be applicable in some variants of commercial vans, this technology is not suited for the pickup truck variants in this segment because of customer demands for towing capability. AAPC commented that concurrent stringency increases in Tier 3/LEV III criteria emission requirements will negatively impact CO₂ and fuel consumption.

GM commented that any attempt to force more stringent regulations than proposed, such as Alternative 4, would be extremely detrimental to manufacturers, consumers, the U.S. economy, and the millions of transportation-related jobs. Daimler similarly commented that the proposed standards would be a challenge for automotive manufacturers. According to the commenter, under certain conditions, a more stringent standard than proposed may necessitate hybridization of the affected vehicle fleet, which would require substantial development and material costs. Daimler recommends that EPA adopt the proposed standard over Alternative 4, as the additional two years of lead-time will be critical for automotive manufacturers in developing the necessary technologies to achieve compliance. Nissan commented that Alternative 4 at 3.5 percent per year stringency level is simply not feasible, as it does not provide the necessary lead-time to enable manufacturers to balance competitive market constraints with the cost of applying new technologies to a limited product offering. Nissan further commented that to the extent that the more stringent alternative is predicated on the adoption of hybrid and electric powertrain technology, Nissan does not believe that such technology is feasible for this market segment.

After considering the comments, EPA believes that the Phase 2 final standards that the agencies are adopting represent the most stringent standards reasonably achievable within the MY 2021–2027 period. The standards are based largely on the same technologies projected to be used in the light-duty fleet with appropriate adjustments for the heavy-duty fleet because of their specific higher load duty cycles. As shown in the tables 28 and 29 above and repeated below, several technologies are projected to be used at very high adoption rates at or near 100 percent including mass reduction, 8-speed transmissions, engine friction reduction, low rolling resistant tires, improved accessories, and aerodynamic drag reductions. For gasoline engines, some commenters noted that downsize turbo

engines which are projected to be used extensively in light-duty vehicles should also be relied on in the heavy-duty analysis, including for HD pickups. As discussed in VI.C.4.vii above, the agencies agree with the comments provided by AAPC that turbo downsizing is likely to be counter-productive in heavy-duty pickups. EPA (and NHTSA in the Method A analysis) thus is projecting the use of downsized turbo engines only for vans. Under heavy loads, turbo downsized engines may have higher CO₂ and fuel consumption than the engine it replaces. For this reason, EPA continues to believe that the technology can only be projected to be available for heavy-duty vans (and not pickups) and, for vans, is projecting its use at 77 to 97 percent. One commenter argued for a standard predicated on a more aggressive penetration rate for cylinder deactivation noting that in the NPRM the agencies only projected cylinder deactivation at an adoption rate of 22 percent of the overall fleet. The commenter believes that an adoption rate of 40 percent would be more appropriate. In response, cylinder deactivation is a gasoline engine technology and EPA is projecting an adoption rate of 56 percent for pickups and an adoption rate of essentially 100 percent for the gasoline engines in vans not projected to be downsized turbo engines (*i.e.* a more aggressive penetration rate than urged by the commenter).

EPA also remains concerned about projecting standards predicated on high levels of hybridization in the heavy-duty pickup and van fleet. Many heavy duty applications need maximum payload and cargo volume which may compete with weight increases and lost cargo volume from hybridization, directly reducing the capability and therefore work factor of the vehicle. Additionally, it is likely not feasible to size a hybridization system to be effective for any high or maximum payload or towing operation without changing the utility of the vehicle. A manufacturer choosing to hybridize a heavy duty vehicle would likely target vans that are primarily used for cargo volumetric capacity reasons where a reasonably sized hybrid system could be incorporated and be effective under typical operation. EPA believes that the final Phase 2 standards will drive the orderly use of technology while still providing enough lead time that manufacturers could meet the standards using technology paths other than high penetration rates of strong hybrids. Thus, the gap in stringency between

light-duty trucks and the Phase 2 standards for HD pickups and vans reflects constraints of the use of some technologies in the heavy-duty market resulting from the intended use of the vehicles to do more work than light-duty trucks.

The proposed rule discussed several considerations that EPA believes remain valid. The NPRM projected that the higher rate of increase in stringency associated with Alternative 4 and the shorter lead time would necessitate the use of a different technology mix under Alternative 4 compared to the Phase 2 standards that the agencies are adopting. The Phase 2 standards are projected to achieve the same final stringency increase as Alternative 4 at about 80 percent of the average per-vehicle cost increase, and without the expected deployment of more advanced technology at high penetration levels. In particular, under EPA's primary analysis, which does not constrain the use of strong hybrids, manufacturers are estimated to deploy strong hybrids in approximately 8 percent of new vehicles (in MY 2027) under the Phase 2 standards, compared to 12 percent under Alternative 4 (in MY 2025). Less aggressive electrification technologies also appear on 33 percent of new vehicles simulated to be produced in MY 2027 under Alternative 4, but are not projected to be necessary under the Phase 2 standards. Additionally, it is important to note that due to the shorter lead time of Alternative 4, there are fewer vehicle refreshes and redesigns during the phase-in period of MY 2021–2025. The longer, shallower phase-in of advanced technologies in the standards that the agencies are adopting allows for more compliance flexibility and closer matching with the vehicle redesign cycles, which (as noted above) can be up to ten years for HD vans. While the Method B CAFE model's algorithm accounts for manufacturers' consideration of upcoming stringency changes and credit carry-forward, the steeper ramp-up of the standard in Alternative 4, coupled with the five-year credit life, results in a prediction that manufacturers would need to take less cost-effective means to comply with the standards compared with the final phase-in period of MY 2021–2027. The public comments from industry commenters confirmed that this is a realistic prediction. For example, the Method B model predicts that some manufacturers will not implement any amount of strong hybrids on their vans during the 2021–2025 timeframe and instead will implement less effective technologies such as mild hybrids at

higher penetration rates. There is also a high degree of sensitivity to the estimated effectiveness levels of individual technologies. At high penetration rates of all technologies on a vehicle, the result of a reduced effectiveness of even a single technology could be non-compliance with the standards. If the standards do not account for this uncertainty, there will be a real possibility that a manufacturer who followed the exact technology path we project will not meet their target because a technology performed slightly differently in their application. In this Method B analysis, EPA considered all comments regarding Alternative 4 and concluded that the longer lead time provided by the Phase 2 standards that the agencies are adopting is necessary as it better matches the redesign cycles for vehicles in this market segment and provides the time necessary for manufacturers to more fully utilize a range of technologies best suited for this market segment. These technologies are projected to be available within the lead time provided under the Phase 2 standards—*i.e.*, by MY 2027, as discussed in RIA Chapter 2.6. These standards will require a relatively aggressive implementation schedule of most of these technologies during the program phase-in. Heavy-duty pickups and vans will need to have a combination of many individual technologies to achieve these standards. These standards are projected to yield significant emission and fuel consumption reductions without requiring a large segment transition to strong hybrids, a technology that while successful in light-duty passenger cars, cross-over vehicles and SUVs, may impact vehicle work capabilities⁵²¹ and have questionable customer acceptance in a large portion of this segment dedicated to towing.⁵²² See discussion above and in Section VI.D.9.

The tables above show that many technologies will be at or potentially approach 100 percent adoption rates according to the analysis. If certain technologies turn out to be not well suited for certain vehicle models or less effective than projected, other technology pathways will be needed.

⁵²¹ As noted earlier, hybrid batteries, motors and electronics generally add weight to a vehicle and require more space which can result in conflicts with payload weight and volume objectives.

⁵²² Hybrid electric systems are not sized for situations when vehicles are required to do trailer towing where the combined weight of vehicle and trailer is 2 to 4 times that of the vehicle alone. During these conditions, the hybrid system will have reduced effectiveness. Sizing the system for trailer towing is prohibitive with respect to hybrid component required sizes and the availability of locations to place larger components like batteries.

The additional lead time provided by the Phase 2 standards reduces these concerns because manufacturers will have more flexibility to implement their compliance strategy and are more likely to do so within a product redesign cycle necessary for many new technologies to be implemented.

The agencies also received comments that the standards should be based exclusively on the GHG capabilities of diesel vehicles. The commenters viewed the separate gasoline and diesel standards as preferential treatment of gasoline-powered vehicles which have inherently higher GHG and fuel consumption. As discussed in Section B.1, the agencies are maintaining the separate gasoline and diesel standards for heavy duty pickups and vans. As discussed earlier, diesel engines are fundamentally more efficient than gasoline engines providing the same power (even gasoline engines with the technologies discussed above) while using less fuel. However, dieselization is not a technology path the agencies included in the analysis for the Phase 1 rule or the Phase 2 rules. Gasoline-powered vehicles account for nearly half of the heavy-duty pickup and van market and are used in applications where a diesel may not make sense from a cost or consumer choice standpoint. Commenters did not address the costs of extensive dieselization.

More stringent standards, including Alternative 4, could result in manufacturers switching from gasoline engines to diesel engines in certain challenging segments. While technologically feasible, EPA remains concerned that this pathway could cause a distortion in consumer choices and significantly increase the cost of those vehicles, particularly considering that more stringent standards are projected to require penetration of some form of hybridization. Also, the agencies did not consider the impact dieselization would have on lead-time, as shifting nearly half the market from gasoline to diesel engines would require substantial retooling of production. Commenters also did not account for the costs or address the feasibility of such retooling in the lead time available under either Phase 2 or Alternative 4. In addition, if dieselization occurs by manufacturers equipping vehicles with larger diesel engines designed for broad coverage of applications typical of this sector rather than “right-sized” engines, the towing capability of the vehicles could increase, resulting in higher work factors for the vehicles, higher targets, and reduced program benefits. Bosch commented that holding gasoline vehicles to the same GHG standards as

diesels would bring the costs of compliance with all emissions standards, including criteria pollutant standards, for gasoline vehicles more in line with diesels, considering the costs of complying with criteria pollutant standards are much higher for diesels compared to gasoline vehicles. In response, EPA's Method B analysis shows that significantly more stringent gasoline vehicle GHG standards may require high levels of hybridization which, as discussed above, may not be acceptable for this market segment. This, in turn, could lead to dieselization, as manufacturers would opt to phase out gasoline-fueled vehicles rather than opt for widespread hybridization of their product offerings. EPA continues to believe that it is reasonable to adopt Phase 2 standards that continue to preserve the opportunity for manufacturers to produce and consumers to choose gasoline-powered vehicles in this market segment.

Based on the information presented here in this Method B analysis, EPA believes that the Phase 2 standards the agencies are finalizing are appropriate within the meaning of CAA section 202(a)(1), for this segment for the model years in question. EPA believes the standards reflect a reasonable consideration of the statutory factors of technology effectiveness, feasibility, cost, lead time, and safety for purposes of CAA sections 202(a)(1) and (2). The

standards are appropriately technology-forcing, predicated on performance of technologies not only currently deployed but those which reasonably can be developed during the phase in period. EPA has indicated how technologies not currently deployed in this sector can be reliably commercialized in the lead time provided by the standard. See above and RIA Chapter 2.5 "Technology Application" where the individual technologies available during the phase-in are described in detail. Note that advanced technologies like strong hybridization will require several years of development prior to commercialization to meet required reliability and durability goals in this sector. As noted, the Method B analysis projects that the additional lead-time provided by the Phase 2 standards allows for the implement CO₂-reducing technologies without the need for significant hybridization and at a significantly lower cost compared to Alternative 4, as shown in the tables above.

EPA has also carefully considered the costs of the standards. The technologies associated with meeting the Phase 2 standards are estimated to add costs to heavy-duty pickups and vans as shown in Table VI-31 for the flat baseline. These costs are the average fleet-wide incremental vehicle costs relative to a vehicle meeting the MY 2018 standard in each of the model years shown.

Reductions associated with these costs and technologies are considerable, estimated at a 16 percent reduction of fuel consumption and CO₂eq emissions from the MY 2018 baseline for gasoline and diesel engine equipped vehicles.⁵²³ As shown by the analysis, the long-term cost effectiveness of the rule is similar to that of the Phase 1 HD pickup and van standards (found by the agencies to be highly cost effective, without consideration of payback), and also falls within the range of the cost effectiveness for Phase 2 standards for the other HD sectors.⁵²⁴ The agencies have already found costs in this range to be cost effective (including for the heavy duty pickup and van sector), independent of the associated fuel savings. 76 FR 57228. EPA reiterates that finding here. Moreover, the cost of controls reflected in potential increased vehicle cost will be fully recovered by the operator due to the associated fuel savings, with a payback period somewhere in the third year of ownership, as shown in Section IX.M of this Preamble. The rules' projected benefits far exceed costs (see IX.K), and costs are actually projected to be negative when fuel savings are considered.

Consistent with EPA's authority under 42 U.S.C. 7521(a) and based on its Method B analysis, EPA is thus finalizing the Phase 2 standards as proposed.

TABLE VI-31—HD PICKUPS AND VANS INCREMENTAL TECHNOLOGY COSTS PER VEHICLE FINAL PHASE 2 STANDARDS VS. FLAT BASELINE

	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027

(2) HD Pickups and Vans Industry Impacts (Method B)

The analysis fleet provides a starting point for estimating the extent to which manufacturers might add fuel-saving (and, therefore, CO₂-avoiding) technologies under various regulatory alternatives, including the no-action alternative that defines a baseline against which to measure estimated impacts of new standards. The analysis fleet is a forward-looking projection of production of new HD pickups and vans, holding vehicle characteristics (e.g., technology content and fuel consumption levels) constant at model year 2014 levels, and adjusting

production volumes based on recent DOE and commercially-available forecasts. This analysis fleet includes some significant changes relative to the market characterization that was used to develop the Phase 1 standards applicable starting in model year 2014; in particular, the analysis fleet includes some new HD vans (e.g., Ford's Transit and Fiat Chrysler's Promaster) that are considerably more fuel-efficient than HD vans these manufacturers have previously produced for the U.S. market.

While the Phase 2 standards are scheduled to begin in model year 2021, the requirements they define are likely

to influence manufacturers' planning decisions several years in advance. This is true in light-duty planning, and is accentuated by the comparatively long redesign cycles and small number of models and platforms offered for sale in the 2b/3 market segment. Additionally, manufacturers will respond to the cost and efficacy of available fuel consumption improvements, the price of fuel, and the requirements of the Phase 1 standards that specify maximum allowable average fuel consumption and GHG levels for MY 2014–MY 2018 HD pickups and vans (the final standard for MY 2018 is held constant for model years 2019 and

⁵²³ See Table VI-27.

⁵²⁴ Analysis using the MOVES model indicates that the cost effectiveness of these standards is \$95

per ton CO₂ eq removed in MY 2030 (RIA Table 7-31), almost identical to the \$90 per ton CO₂ eq removed (MY 2030) which the agencies found to be

highly cost effective for these same vehicles in Phase 1. See 76 FR 57228.

2020). The forward-looking nature of product plans that determine which vehicle models will be offered in the model years affected by these standards lead to additional technology application to vehicles in the analysis fleet that occurs in the years prior to the start of these standards. From the industry perspective, this means that manufacturers will incur costs to comply with these standards in the baseline and that the total cost of the regulations will include some costs that occur prior to their start, and represent incremental changes over a world in which manufacturers will have already modified their vehicle offerings compared to today.

TABLE VI-32—MY 2021 METHOD B BASELINE COSTS FOR MANUFACTURERS IN 2b/3 MARKET SEGMENT IN THE DYNAMIC BASELINE, OR ALTERNATIVE 1b

Manufacturer	Average technology cost (\$)	Total cost increase (\$m)
Fiat Chrysler	275	27
Daimler	18	0
Ford	258	78
General Motors	782	191
Nissan	282	3
Industry	442	300

As Table VI-32 shows, the industry as a whole is expected to add about \$440 of new technology to each new vehicle model by 2021 under the no-action alternative defined by the Phase 1 standards. Reflecting differences in projected product offerings in the analysis fleet, some manufacturers (notably Daimler) are significantly less constrained by the Phase 1 standards than others and face lower cost increases as a result. General Motors (GM) shows the largest increase in average vehicle cost, but results for GM's closest competitors (Ford and Fiat Chrysler) do not include the costs of their recent van redesigns, which are already present in the analysis fleet (discussed in greater detail below).

The above results reflect the assumption that manufacturers having achieved compliance with standards might act as if buyers are willing to pay for further fuel consumption improvements that "pay back" within 6 months (*i.e.*, those improvements whose incremental costs are exceeded by

savings on fuel within the first six months of ownership). It is also possible that manufacturers will choose not to migrate cost-effective technologies to the 2b/3 market segment from similar vehicles in the light-duty market. Resultant technology costs in model year 2021 results for the no-action alternative, summarized in Table VI-33 below, are quite similar to those shown above for the 6-month payback period. Due to the similarity between the two baseline characterizations, results in the following discussion represent differences relative to only the 6-month payback baseline.

TABLE VI-33—MY 2021 METHOD B BASELINE COSTS FOR HD PICKUPS AND VANS IN THE FLAT BASELINE, OR ALTERNATIVE 1a

Manufacturer	Average technology cost (\$)	Total cost increase (\$m)
Fiat Chrysler	268	27
Daimler	0	0
Ford	248	75
General Motors	767	188
Nissan	257	3
Industry	431	292

The results below represent the impacts of several regulatory alternatives, including those defined by the Phase 2 standards, as incremental changes over the baseline, where the baseline is defined as the state of the world in the absence of this regulatory action (but, of course, including the Phase 1 standards). Large-scale, macroeconomic conditions like fuel prices are constant across all alternatives, including the baseline, as are the fuel economy improvements under the no-action alternative defined by the Phase 1 rule that covers model years 2014–2018 and is constant from model year 2018 through 2020. In the baseline scenario, the Phase 1 standards are assumed to remain in place and at 2018 levels throughout the analysis (*i.e.* MY 2030). The only difference between the definitions of the alternatives is the stringency of these standards starting in MY 2021 and continuing through either MY 2025 or MY 2027, and all of the differences in outcomes across alternatives are attributable to differences in the standards.

The standards vary in stringency across regulatory alternatives (1–5), but

as discussed above, all of the standards are based on the curve developed in the Phase 1 standards that relate fuel economy and GHG emissions to a vehicle's work factor. The alternatives considered here represent different rates of annual increase in the curve defined for model year 2018, growing from a 0 percent annual increase (Alternative 1, the baseline or "no-action" alternative) up to a 4 percent annual increase (Alternative 5). Table VI-34 shows a summary⁵²⁵ of outcomes by alternative incremental to the baseline (Alternative 1b) for Model Year 2030⁵²⁶, with the exception of technology penetration rates, which are absolute.

The technologies applied as inputs to the CAFE model (in either its Method B or A iterations) have been grouped (in most cases) to give readers a general sense of which types of technology are applied more frequently than others, and are more likely to be offered in new class 2b/3 vehicles once manufacturers are fully compliant with the standards in the alternative. Model year 2030 was chosen to account for technology application that occurs once the standards have stabilized, but manufacturers are still redesigning products to achieve compliance—generating technology costs and benefits in those model years. The summaries of technology penetration are also intended to reflect the relationship between technology application and cost increases across the alternatives. The table rows present the degree to which specific technologies are predicted to be present in new class 2b and class 3 vehicles in 2030, and correspond to: Variable valve timing (VVT) and/or variable valve lift (VVL), cylinder deactivation, direct injection, engine turbocharging, 8-speed automatic transmissions, electric power-steering and accessory improvements, micro-hybridization (which reduces engine idle, but does not assist propulsion), full hybridization (integrated starter generator or strong hybrid that assists propulsion and recaptures braking energy), and aerodynamic improvements to the vehicle shape. In addition to the technologies in the following tables, there are some lower-complexity technologies that have high market penetration across all the alternatives and manufacturers; low rolling-resistance tires, low friction lubricants, and reduced engine friction are examples.

that today's analysis estimates some earning and application of "carried forward" compliance credits, the model was run extending the analysis through model year 2030.

⁵²⁵ NHTSA generated hundreds of outputs related to economic and environmental impacts, each available technology, and the costs associated with the rule. A more comprehensive treatment of these outputs appears in Chapter 10 of the RIA.

⁵²⁶ As noted above, the NHTSA CAFE model estimates that redesign schedules will "straddle" model year 2027, the latest year for which the agencies are increasing the stringency of fuel consumption and GHG standards. Considering also

Notes:^a Includes mild hybrids (ISG) and strong HEVs.^b Values used in Methods A & B^c Values used in Method A, calculated using a 3% discount rate.

In general, as stated above, the Method B model projected that the standards will cause manufacturers to produce HD pickups and vans that are lighter, more aerodynamic, and more technologically complex across all the alternatives. As Table VI-34 shows, there is a difference between the relatively small increases in required fuel economy and average incremental technology cost between the alternatives, suggesting that the challenge of improving fuel consumption and CO₂ emissions accelerates as stringency increases (*i.e.*, that there may be a “knee” in the relationship between technology cost and reductions in fuel consumption/GHG emissions).

The contrast between alternatives 3 and 4 is even more prominent, with an

identical required fuel economy improvement projected to lead to price increases greater than 20 percent based on the more rapid rate of increase and shorter time span of Alternative 4, which achieves all of its increases by MY 2025 while Alternative 3 continues to increase at a slower rate until MY 2027. Despite these differences, the increase in average payback period when moving from Alternative 3 to Alternative 4 to Alternative 5 is fairly constant at around an additional three months for each jump in stringency.

Manufacturers offer few models, typically only a pickup truck and/or a cargo van, and while there are a large number of variants of each model, the degree of component sharing across the variants can make diversified technology application either

economically impractical or impossible. This forces manufacturers to apply some technologies more broadly in order to achieve compliance than they might do in other market segments (passenger cars, for example). This difference between broad and narrow application—where some technologies must be applied to entire platforms, while some can be applied to individual model variants—also explains why certain technology penetration rates decrease between alternatives of increasing stringency (cylinder deactivation or mass reductions in Table VI-34, for example). For those cases, narrowly applying a more advanced (and costly) technology can be a more cost effective path to compliance and lead to reductions in the amount of

lower-complexity technology that is applied.

As noted in Section E.1 above, one driver of the change in technology cost between Alternative 3 and Alternative 4 in the Method B analysis is the amount of hybridization projected to result from the implementation of the standards. While only about 5 percent full hybridization (defined as either integrated starter-generator or strong hybrid) is expected to be needed to comply with Alternative 3, the higher rate of increase and compressed schedule moving from Alternative 3 to

Alternative 4 is enough to increase the percentage of the fleet adopting full hybridization by a factor of two. To the extent that manufacturers are concerned about introducing hybrid vehicles in the 2b and 3 market, it is worth noting that new vehicles subject to Alternative 3 achieve the same fuel economy as new vehicle subject to Alternative 4 by 2030, with less full hybridization projected under this Method B analysis as being needed to achieve the improvement.

The alternatives also lead to important differences in outcomes at the manufacturer level, both from the

industry average and from each other. General Motors, Ford, and Fiat Chrysler, are expected to have approximately 95 percent of the 2b/3 new vehicle market during the years that these standards are being phased in. Due to their importance to this market and the similarities between their model offerings, these three manufacturers are discussed together and a summary of the way each is impacted by the standards appears below in Table VI–35, Table VI–36 and Table VI–37 for General Motors, Ford, and Fiat Chrysler, respectively.

The fuel consumption and GHG standards require manufacturers to achieve an average level of compliance, represented by a sales-weighted average across the specific targets of all vehicles offered for sale in a given model year, such that each manufacturer will have a unique required consumption/emissions level determined by the composition of its fleet, as illustrated above. However, there are more interesting differences than the small differences in required fuel economy levels among manufacturers. In particular, the average incremental technology cost increases with the stringency of the alternative for each manufacturer, but the size of the cost increase from one alternative to the next varies among them, with General Motors showing considerably larger increases in cost moving from Alternative 3 to Alternative 4, than from either Alternative 2 to Alternative 3 or Alternative 4 to Alternative 5. Ford is estimated to have more uniform cost increases from each alternative to the next, in increasing stringency, though still benefits from the reduced pace and longer period of increase associated with Alternative 3 compared to Alternative 4.

The Method B simulation results show all three manufacturers facing cost increases when the stringency of the standards move from 2.5 percent annual increases over the period from MY 2021–2027 to 3.5 percent annual increases from MY 2021–2025, but General Motors has the largest at 75 percent more than the industry average price increase for Alternative 4. GM also faces higher cost increases in Alternative 2 about 50 percent more than either Ford or Fiat Chrysler. And for the most stringent alternative considered, EPA estimates that General

Motors will face average cost increases of more than \$2,700, in addition to the more than \$700 increase in the baseline—approaching nearly \$3,500 per vehicle over today's prices.

Technology choices also differ by manufacturer, and some of those decisions are directly responsible for the largest cost discrepancies. For example, in this Method B analysis, GM is estimated to engage in the least amount of mass reduction among the Big 3 after Phase 1, and much less than Fiat Chrysler, but reduces average vehicle mass by over 300 lbs. in the baseline—suggesting that some of GM's easiest Phase 1 compliance opportunities can be found in lightweighting technologies. Similarly, Fiat Chrysler is projected to apply less hybridization than the others, and much less than General Motors, which is simulated in Alternative 4 to have full hybrids (either integrated starter generator or complete hybrid system) on all of its fleet by 2030, nearly 20 percent of which will be strong hybrids, and the strong hybrid share decreases to about 18 percent in Alternative 5, as some lower level technologies are applied more broadly. Because the analysis applies the same technology inputs and the same logic for selecting among available opportunities to apply technology, the unique situation of each manufacturer determined which technology path is projected as the most cost-effective.

In order to understand the differences in incremental technology costs and fuel economy achievement across manufacturers in this market segment, it is important to understand the differences in their starting position relative to these standards. One important factor, made more obvious in the following figures, is the difference between the fuel economy and

performance of the recently redesigned vans offered by Fiat Chrysler and Ford (the Promaster and Transit, respectively), and the more traditionally-styled vans that continue to be offered by General Motors (the Express/Savannah). In MY 2014, Ford began the phase-out of the Econoline van platform, moving those volumes to the Euro-style Transit vans (discussed in more detail in Section VI.D.2). The Transit platform represents a significant improvement over the existing Econoline platform from the perspective of fuel economy, and for the purpose of complying with the standards, the relationship between the Transit's work factor and fuel economy is a more favorable one than the Econoline vans it replaces. Since the redesign of van offerings from both Fiat Chrysler and Ford occur in (or prior to) the 2014 model year, the costs, fuel consumption improvements, and reductions of vehicle mass associated with those redesigns are included in the analysis fleet, meaning they are not carried forward as part of the compliance modeling exercise. By contrast, General Motors is simulated to redesign their van offerings after 2014, such that there is a greater potential for these vehicles to incur additional costs attributable to new standards, unlike the costs associated with the recent redesigns of their competitors. The inclusion of these new Ford and Fiat Chrysler products in the analysis fleet is the primary driver of the cost discrepancy between GM and its competitors in both the baseline and Alternative 2 in this Method B analysis, when Ford and Fiat Chrysler have to apply considerably less technology to achieve compliance.

The remaining 5 percent of the 2b/3 market is attributed to two manufacturers, Daimler and Nissan,

which, unlike the other manufacturers in this market segment, only produce vans. The vans offered by both manufacturers currently utilize two engines and two transmissions, although both Nissan engines are gasoline engines and both Daimler engines are diesels. Despite the logical grouping, these two manufacturers are

projected to be impacted much differently by these standards. For the least stringent alternative considered, Daimler is projected to add no technology and incurs no incremental cost in order to comply with the standards. At stringency increases greater than or equal to 3.5 percent per year, Daimler only really improves some

of their transmissions and improves the electrical accessories of its Sprinter vans. By contrast, Nissan's starting position is much weaker and their compliance costs closer to the industry average in Table VI-34. This difference could increase if the analysis fleet supporting the final rule includes forthcoming Nissan HD pickups.

As Table VI-38 and Table VI-39 show, Nissan is projected to apply more technology than Daimler in the less stringent alternatives and significantly more technology with increasing stringency. The Euro-style Sprinter vans that comprise all of Daimler's model offerings in this segment put Daimler in a favorable position. However, those vans are already advanced—containing downsized diesel engines and advanced aerodynamic profiles. Much like the Ford Transit vans, the recent improvements to the Sprinter vans occurred outside the scope of the compliance modeling so the costs of the improvements are not captured in the analysis.

Although Daimler's required fuel economy level is much higher than Nissan's (in miles per gallon), Nissan starts from a much weaker position than Daimler and must incorporate additional engine, transmission, platform-level technologies (e.g., mass reduction and aerodynamic improvements) in order to achieve compliance. In fact, more than 25 percent of Nissan's van offerings are projected to contain integrated starter generators by 2030 in Alternative 5.

While the model does not allow sales volumes for any manufacturer (or model) to vary across regulatory

alternatives in the analysis, it is conceivable that under the most stringent alternatives individual manufacturers could lose market share to their competitors if the prices of their new vehicles rise more than the industry average without compensating fuel savings and/or changes to other features.

F. Compliance and Flexibility for HD Pickup and Van Standards

(1) Averaging, Banking, and Trading

The Phase 1 program established substantial flexibility in how manufacturers can choose to implement EPA and NHTSA standards while preserving the benefits for the environment and for energy consumption and security. Primary among these flexibilities are the gradual phase-in schedule, and the corporate fleet average approach which encompasses averaging, banking and trading described below. See Section IV.A. of the Phase 1 Preamble (76 FR 57238) for additional discussion of the Phase 1 averaging, banking, and trading and Section IV.A (3) of the Phase 1 Preamble (76 FR 57243) for a discussion of the credit calculation methodology.

Manufacturers in this category typically offer gasoline and diesel

versions of HD pickup and van vehicle models. The agencies established chassis-based Phase 1 standards that are equivalent in terms of stringency for gasoline and diesel vehicles and are continuing this same approach to stringency for Phase 2. In Phase 1, the agencies established that HD pickups and vans are treated as one large averaging set that includes both gasoline and diesel vehicles⁵²⁷ and the agencies will maintain this averaging set approach for Phase 2, as discussed above in Section VI.B.

As explained in Section II.C.(3) of the Phase 1 Preamble (76 FR 57167), and in Section VI.B (3) above, the program is structured so that final compliance is determined at the end of each model year, when production for the model year is complete. At that point, each manufacturer calculates production-weighted fleet average CO₂ emission and fuel consumption rates along with its production-weighted fleet average standard. Under this approach, a manufacturer's HD pickup and van fleet that achieves a fleet average CO₂ or fuel consumption level better than its

⁵²⁷ See 40 CFR 1037.104(d) and the proposed 40 CFR 86.1819-14(d). Credits may not be transferred or traded between this vehicle averaging set and loose engines or other heavy-duty categories, as discussed in Section I.

standard will be allowed to generate credits. Conversely, if the fleet average CO₂ or fuel consumption level does not meet its standard, the fleet will incur debits (also referred to as a shortfall).

A manufacturer whose fleet generates credits in a given model year will have several options for using those credits to offset emissions from other HD pickups and vans. These options include credit carry-back, credit carry-forward, and credit trading within the HD pickup and van averaging set. These types of credit provisions also exist in the light-duty 2012–2016 and 2017–2025 MY vehicle rules, as well as many other mobile source standards issued by EPA under the CAA. The manufacturer will be able to carry back credits to offset a deficit that had accrued in a prior model year and was subsequently carried over to the current model year, with a limitation on the carry-back of credits to three model years. After satisfying any need to offset pre-existing deficits, a manufacturer may bank remaining credits for use in future years, with a limitation on the carry-forward of credits to five model years. Averaging vehicle credits with engine credits or between vehicle weight classes is not allowed, as discussed in Section I. The agencies did not propose and are not adopting any changes to any of these provisions for the Phase 2 program.

While the agencies proposed to retain 5 year carry-forward of credits for all HD sectors, the agencies requested comment on the merits of a temporary credit carry-forward period of longer than 5 years for HD pickups and vans, allowing Phase 1 credits generated in MYs 2014–2019 to be used through MY 2027. 80 FR 40388. The agencies received several comments regarding credit carry-forward. AAPC commented that manufacturers should be allowed to carry-forward credits indefinitely until they are used to offset a deficit. AAPC commented that longer credit life better aligns with the longer redesign cycles and the smaller production volumes for HD vehicles compared to light-duty vehicles. AAPC also commented that longer credit life would motivate earlier introduction of technology and lower compliance costs, while not changing the overall effectiveness of the program. Nissan and Daimler commented in support of a one-time credit carry-forward that would allow Phase 1 credits to be used through MY 2027. The UAW also generally supported extended credit carry-forward. The agencies also received comments from CARB that the agencies should not allow Phase 1 credits to be carried forward into Phase 2. CARB commented that Phase 1 credits should be limited to

a three year carry-forward or MY 2020 whichever is sooner. CARB is concerned that Phase 1 credits may reduce the efficacy of the Phase 2 program and delay technology development progress.

As noted above, the agencies are retaining the 5 year credit carry-forward provisions as proposed for HD pickups and vans. As discussed in Section VI.C., the agencies believe that the standards are feasible without extending the credit carry-forward provisions. The agencies continue to believe that credit carry-forward provides important flexibility to manufacturer especially in transitioning to more stringent standards and restricting the provision could be disruptive to manufacturer product plans. However, the agencies understand CARB's concerns regarding Phase 1 credits being used to postpone technology progress if some manufacturers were to accumulate large credit banks under Phase 1. Large banks of Phase 1 credits combined with unlimited credit-forward could have the unintended effect of allowing some manufacturers to delay the application of Phase 2 technologies. The 5 year credit carry-forward preserves needed flexibility for transitioning to more stringent Phase 2 standards while also helping to address concerns regarding delaying the introduction of technology in Phase 2 for HD pickups and vans. As discussed in Section I.C.(1)(b)(i), the agencies are extending credit life for certain vocational vehicle subcategories during the transition to the Phase 2 standards. We are doing this for two reasons. First, some manufacturers in these in categories do not have diversified production, which limits the extent to which they can use ABT. Second, the Phase 1 program offer little opportunity for manufacturers to build up their credit balances. Neither of these reasons apply for HD pickups and vans.

As discussed in Section VI.B.4., EPA and NHTSA are changing the HD pickup and van useful life for GHG emissions and fuel consumption from the current 11 years/120,000 miles to 15 years/150,000 miles to make the useful life for GHG emissions consistent with the useful life of criteria pollutants recently updated in the Tier 3 rule. As shown in the Equation VI.1 credits calculation formula below, established by the Phase 1 rule, useful life in miles is a multiplicative factor included in the calculation of CO₂ and fuel consumption credits. In order to ensure banked credits maintain their value in the transition from Phase 1 to Phase 2, NHTSA and EPA proposed and are finalizing an adjustment factor of 1.25 (i.e., 150,000 ÷ 120,000) for credits that are carried forward from Phase 1 to the

MY 2021 and later Phase 2 standards. Without this adjustment factor, the change in useful life would effectively result in a discount of banked credits that are carried forward from Phase 1 to Phase 2, which is not the intent of the change in the useful life. Consider, for example, a vehicle configuration with annual sales of 1,000 vehicles that was 10 g/mile below the standard. Under Phase 1, those vehicles would generate 1,200 Mg of credit (10 × 1,000 × 120,000 ÷ 1,000,000). Under Phase 2, the same vehicles would generate 1,500 Mg of credit (10 × 1,000 × 150,000 ÷ 1,000,000). The agencies do not believe that this adjustment results in a loss of program benefits because there is little or no deterioration anticipated for CO₂ emissions and fuel consumption over the life of the vehicles. Also, as described in the standards and feasibility sections above, the carry-forward of credits is an integral part of the program, helping to smoothing the transition to the new Phase 2 standards. The agencies believe that effectively discounting carry-forward credits from Phase 1 to Phase 2 is unnecessary and could negatively impact the feasibility of the Phase 2 standards.

Equation VI.1 Total Model Year Credit (Debit) Calculation

CO₂ Credits (Mg) = [(CO₂ Std – CO₂ Act) × Volume × UL] ÷ 1,000,000

Fuel Consumption Credits (gallons) = (FC Std – FC Act) × Volume × UL × 100

Where:

CO₂ Std = Fleet average CO₂ standard (g/mi)

FC Std = Fleet average fuel consumption standard (gal/100 mile)

CO₂ Act = Fleet average actual CO₂ value (g/mi)

FC Act = Fleet average actual fuel consumption value (gal/100 mile)

Volume = the total production of vehicles in the regulatory category

UL = the useful life for the regulatory category (miles)

Manufacturers provided comments in support of applying the adjustment factor discussed above. CARB recommended not including the adjustment factor. CARB commented that the adjustment would take benefits achieved under the Phase 1 program and allow them to be used to reduce the potential benefits of Phase 2 standards. The agencies do not view the 1.25 adjustment as reducing the benefits of the program because the adjustment to the Phase 1 credits is completely offset by the increase in the useful life used in the Phase 2 credits calculation shown above. In other words, when the Phase 1 credits are used in Phase 2, 1.25 times more credits will be needed to cover a deficit than would be needed under

Phase 1. The agencies continue to believe this is a reasonable and indeed, necessary, way to address the change in useful life as it applies to the credits calculations.

(2) Advanced Technology Credits

The Phase 1 program included on an interim basis advanced technology credits for MYs 2014 and later in the form of a multiplier of 1.5 for the following technologies:

- Hybrid powertrain designs that include energy storage systems
- Waste heat recovery
- All-electric vehicles
- Fuel cell vehicles

The advanced technology credit program is intended to encourage early development of technologies that are not yet commercially available. This multiplier approach means that each advanced technology vehicle will count as 1.5 vehicles in a manufacturer's compliance calculation.⁵²⁸ The advanced technology multipliers were included on an interim basis in the Phase 1 program and the incentive multipliers included for Phase 1 and the 1.5 multiplier incentive adopted for Phase 1 will end beginning in MY 2021, when the more stringent Phase 2 standards are to begin phase-in. However, the agencies are including new incentive multipliers for Phase 2 for PHEVs, EVs, and fuel cell vehicles.

As discussed in Section I, the agencies requested comment on whether or not the incentive multiplier credits should be extended to later model years for more advanced technologies such as EVs and fuel cell vehicles. These technologies are not projected to be part of the technology path used by manufacturers to meet the Phase 2 standards for HD pickups and vans. EV and fuel cell technologies will presumably need to overcome the highest hurdles to commercialization for HD pickups and vans in the time frame of the final rules, and also have the potential to provide the highest level of benefit. The agencies received several comments encouraging the agencies to continue advanced technology multipliers in Phase 2 for heavy-duty vehicles. After considering these comments, and considering that EV and

fuel technologies have the potential for more significant emission reductions and fuel consumption savings than any of the technologies projected to be used for Phase 2 compliance, the agencies are adopting new incentive multipliers for Phase 2 for these technologies for all heavy-duty vehicle sectors. A detailed discussion of these provisions is provided above in Section I.

NHTSA and EPA established that for Phase 1, EVs and other zero tailpipe emission vehicles be factored into the fleet average GHG and fuel consumption calculations based on the diesel standards targets for their model year and work factor. The agencies also established for electric and zero emission vehicles that in the credits equation the actual emissions and fuel consumption performance be set to zero (*i.e.*, that emissions be considered on a tailpipe basis exclusively) rather than including upstream emissions or energy consumption associated with electricity generation. As we look to the future, we are not projecting the adoption of electric HD pickups and vans into the heavy duty market; therefore, we believe that this provision is still appropriate. Unlike the MY 2012–2016 light-duty rule, which adopted a cap whereby upstream emissions will be counted after a certain volume of sales (see 75 FR 25434–25436), we believe there is no need to a cap for HD pickups and vans because of the infrequent projected use of EV technologies in the Phase 2 timeframe. In Phase 2, we thus continue to deem electric vehicles as having zero CO₂, CH₄, and N₂O emissions as well as zero fuel consumption. See Section I for a discussion of the treatment of lifecycle emissions for alternative fuel vehicles, including comments regarding the treatment of upstream emissions, and Section XI for the treatment of lifecycle emissions for natural gas specifically.

(3) Off-Cycle Technology Credits

The Phase 1 program established an opportunity for manufacturers to generate credits by applying innovative technologies whose CO₂ and fuel consumption benefits are not captured on the 2-cycle test procedure (*i.e.*, off-cycle).⁵²⁹ For HD pickups and vans, the approach for off-cycle technologies established in Phase 1 is similar to that established for light-duty vehicles due to the use of the same basic chassis test procedures. The agencies are retaining

this approach for Phase 2 as proposed. See 80 FR 40389. To generate credits, manufacturers are required to submit data and a methodology for determining the level of credits for the off-cycle technology subject to EPA and NHTSA review and approval. The application for off-cycle technology credits is also subject to a public evaluation process and comment period. EPA and NHTSA would approve the methodology and credits only if certain criteria were met. Baseline emissions and fuel consumption⁵³⁰ and control emissions and fuel consumption need to be clearly demonstrated over a wide range of real world driving conditions and over a sufficient number of vehicles to address issues of uncertainty with the data. Data must be on a vehicle model-specific basis unless a manufacturer demonstrated model-specific data were not necessary. Once a complete application is submitted by the manufacturer, the regulations require that the agencies publish a notice of availability in the **Federal Register** notifying the public of a manufacturer's off-cycle credit calculation methodology and provide opportunity for comment.

EPA and NHTSA requested comment on establishing a pre-defined technology menu list for HD pickups and vans similar to the approach adopted for light-duty vehicles in the MY 2017–2025 rule.⁵³¹ As with the light-duty vehicle program, the agencies noted that a pre-defined list could simplify the process for generating off-cycle credits and may further encourage the introduction of these technologies. However, the agencies also noted that appropriate default level of credits for the heavier vehicles would need to be established. The agencies requested comments with supporting HD pickup and van specific data and analysis that would provide a substantive basis for appropriate credits levels for the HD pickup and van category. The data and analysis would need to demonstrate that the pre-defined credit level represents real-world emissions reductions and fuel consumption improvements not captured by the 2-cycle test procedures.

The agencies received comments recommending off-cycle credits for over a dozen technologies. There are three primary reasons that the agencies are not adopting credits for the individual technologies recommended by commenters. In many cases, the analysis provided by commenters did not

⁵²⁸ EPA and NHTSA similarly included temporary advanced technology multipliers in the light-duty 2017–2025 program, believing it was worthwhile to forego modest additional emissions reductions and fuel consumption improvements in the near-term in order to lay the foundation for the potential for much larger “game-changing” GHG and oil consumption reductions in the longer term. The incentives in the light-duty vehicle program are available through the 2021 model year. See 77 FR 62811, October 15, 2012.

⁵²⁹ See 76 FR 57251, September 15, 2011, 40 CFR 1037.104(d)(13), and 40 CFR 86.1819–14(d)(13). Note that for the vocational vehicle and tractor standards, and off-cycle credit is to evaluate technologies whose benefit is not recognized by GEM (rather than the two-cycle test). See V.D.3 and III.F.3, respectively.

⁵³⁰ Fuel consumption is derived from measured CO₂ emissions using conversion factors of 8,887 g CO₂/gallon for gasoline and 10,180 g CO₂/gallon for diesel fuel.

⁵³¹ 77 FR 62832–62839, October 15, 2012.

include sufficient real-world heavy-duty vehicle data on which to base the menu credit value recommended by the commenter. Thus, in several cases, the analysis provided by commenters was based on light-duty vehicle data or on simulations with little detail provided, which analysis is not directly applicable to heavy duty pickups and vans for purposes of technology performance quantification. Second, in several cases, the technologies recommended for off-cycle credits for pickups and vans provide significant on-cycle benefit. Such technologies are considered to be adequately captured by the test procedures (within the meaning of section 86.1819–14(d)(13))⁵³² and are not considered to be eligible for off-cycle credits. Examples of adequately captured technologies that commenters recommended for off-cycle credits include cylinder deactivation and cooled EGR. Moreover, these are technologies the agencies expect to be in the mix of technologies used to meet the standards (and are projected to be used in the respective analyses of compliance paths on which the stringency of the final standards are predicated). EPA has already indicated that off-cycle credits are not available for technologies that form part of the technology basis for the greenhouse gas standards because these technologies' benefits would already be reflected in the standard's stringencies (and costs). 77 FR 62835 (Oct. 12, 2012). Indeed, it is because of these technologies' robust performance in two-cycle space that the agencies have projected their use as part of the compliance path on which standard stringency is predicated. Likewise, many of these technologies are inherent to vehicle design and so are similarly ineligible. *Id.* at 62732, 62836. Finally, a few other recommended technologies are considered safety-related technologies not eligible for credits because they could reasonably be expected to fall under vehicle safety standards in the future and so would be adopted in any case. Granting off-cycle credits for these technologies consequently would amount to an unwarranted windfall. Adaptive cruise control and forward collision warning systems are examples of these technologies. Chapter 7 of the Response

⁵³² This provision states that an off-cycle credit must be for a technology that is "not adequately captured on the Federal Test procedure (FTP) and/or the highway Fuel Economy Test (HFET)." EPA has indicated that this requires manufacturers to demonstrate "an incremental off-cycle benefit that is significantly greater than the 2-cycle benefit." 77 FR 62836 (Oct. 12, 2012).

to Comments for this final rule provides a detailed response to these comments

(4) Demonstrating Compliance for Heavy-Duty Pickup Trucks and Vans

The Phase 1 rule established a comprehensive compliance program for HD pickups and vans that NHTSA and EPA are generally retaining for Phase 2. The compliance provisions cover details regarding the implementation of the fleet average standards including vehicle certification, demonstrating compliance at the end of the model year, in-use standards and testing, carryover of certification test data, and reporting requirements. Please see Section V.B.(1) of the Phase 1 rule Preamble (76 FR 57256–57263) for a detailed discussion of these provisions.

The Phase 1 rule contains special provisions regarding loose engines and optional chassis certification of certain vocational vehicles over 14,000 lbs. GVWR. As proposed, the agencies are extending the optional chassis certification provisions to Phase 2 and are providing a temporary loose engine provision for Phase 2 as described in Section V.D.3.e, under Compliance Flexibility Provisions. See the vocational vehicle Section V.D. and XIII.A.2 for a detailed discussion of the rule for optional chassis certification and Section II.D. for the discussion of loose engines.

VII. Aggregate GHG, Fuel Consumption, and Climate Impacts

Given that the purpose of setting these Phase 2 standards is to reduce fuel consumption and greenhouse gas (GHG) emissions from heavy-duty vehicles, it is necessary for the agencies to analyze the extent to which these standards will accomplish that purpose. This section describes the agencies' methodologies for projecting the reductions in greenhouse gas (GHG) emissions and fuel consumption and the methodologies the agencies used to quantify the impacts associated with these standards. In addition, EPA's analyses of the projected change in atmospheric carbon dioxide (CO₂) concentration and consequent climate change impacts are discussed. Because of NHTSA's obligations under EPCA/EISA and NEPA, NHTSA further analyzes the projected environmental impacts related to fuel consumption, GHG emissions, and climate change, for each regulatory alternative. Detailed documentation of this analysis is provided in Chapters 3, 4 and 5 of NHTSA's FEIS accompanying today's notice.

A. What methodologies did the Agencies use to project GHG emissions and fuel consumption impacts?

Different tools exist for estimating potential fuel consumption and GHG emissions impacts associated with fuel efficiency and GHG emission standards. One such tool is EPA's official mobile source emissions inventory model named Motor Vehicle Emissions Simulator (MOVES).⁵³³ The agencies used a revised version of MOVES2014a to quantify the impacts of these standards for vocational vehicles and combination tractor-trailers on GHG emissions and fuel consumption.

Since the notice of proposed rulemaking, EPA has made certain updates to MOVES in response to the public comments on the proposal: (1) The projections of vehicle sales, populations, and activity in the version used for the final rulemaking were updated to incorporate the latest projections from the U.S. Department of Energy's Annual Energy Outlook 2015 report;⁵³⁴ (2) the extended idle and APU emission rates in MOVES were updated based on the analyses of latest test programs that reflect the current prevalence of clean idle certified engines; and (3) the baseline adoption rates of idle reduction technology were reassessed and projected to be lower than what was assumed in the proposal, as described in Section III.D.1.a of the Preamble. In addition, changes to APU emissions rates for PM_{2.5} were implemented in MOVES reflecting the fact that EPA is adopting requirements to control PM_{2.5} emissions from APUs installed in new tractors, as discussed in Section III.C.3 of the Preamble. Finally, methodological improvements were made in classifying vehicle types and in forecasting vehicle populations and activity. The aforementioned updates above, along with other changes, are documented in the memorandum to the docket.⁵³⁵

MOVES was run with user input databases, described in more detail below, that reflected the projected technological improvements resulting from the final rules, such as the improvements in engine and vehicle efficiency, aerodynamic drag, and tire rolling resistance. The changes made to

⁵³³ MOVES homepage: <https://www3.epa.gov/otaq/models/moves/index.htm> (last accessed May 27, 2016).

⁵³⁵ U.S. EPA. Updates to MOVES for Emissions Analysis of Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2 FRM. Docket No. EPA-HQ-OAR-2016. July 2016.

the default MOVES database are described below in Section VII.B.(3). All the input data, MOVES run spec files, and the scripts used for the analysis, as well as the version of MOVES used to generate the emissions inventories, can be found in the docket.⁵³⁶

Another such tool is DOT's CAFE model, which estimates how manufacturers could potentially apply technology improvements in response to new standards, and then calculates, among other things, resultant changes in national fuel consumption and GHG emissions. As described in Section VI, two versions of this model were used for analysis of potential new standards for HD pickups and vans. Both versions use the work-based attribute metric of "work factor" established in the Phase 1 rule for heavy-duty pickups and vans instead of the light-duty "footprint" attribute metric. The CAFE model takes user-specified inputs on, among other things, vehicles that are projected to be produced in a given model year, technologies available to improve fuel efficiency on those vehicles, potential regulatory standards that will drive improvements in fuel efficiency, and economic assumptions. The CAFE model takes every vehicle in each manufacturer's fleet and decides what technologies to add to those vehicles in order to allow each manufacturer to comply with the standards in the most cost-effective way. Based on those results, the CAFE model then calculates total fuel consumption and GHG emissions impacts based on those inputs, along with economic costs and benefits. The DOT's CAFE model is further described in detail in Section VI of the Preamble and Chapter 10 of the RIA.

For these rules, the agencies used two analytical methods for the heavy-duty pickup and van segment employing both DOT's CAFE model and EPA's MOVES model. The agencies used EPA's MOVES model to estimate fuel consumption and emissions impacts for tractor-trailers (including the engine that powers the tractor) and vocational vehicles (including the engine that powers the vehicle).

For heavy-duty pickups and vans, the agencies performed separate analyses, which we refer to as "Method A" and "Method B." In Method A, a modified version of the CAFE model was used to project a pathway the industry could use to comply with each regulatory alternative and the estimated effects on

fuel consumption, emissions, benefits and costs. In Method B, the MOVES model was used to estimate fuel consumption and emissions from these vehicles. NHTSA considered Method A as its central analysis. EPA considered the results of Method B as its central analysis. The agencies concluded that these methods led the agencies to the same conclusions and the same selection of the final standards. See Chapter 5 of the RIA for additional discussions of these two methods.

For both methods, the agencies analyzed the impact of the final rules, relative to two different reference cases—"flat" (Alternative 1a) and "dynamic" (Alternative 1b). The flat baseline projects very little improvement in new vehicles in the absence of new Phase 2 standards. In contrast, the dynamic baseline projects more improvements in vehicle fuel efficiency in the absence of new Phase 2 standards. The agencies considered both reference cases (for additional details, see Chapter 11 of the RIA). The results for all of the regulatory alternatives relative to both reference cases, derived via the same methodologies discussed in this section, are presented in Section X of the Preamble.

For brevity, a subset of these analyses are presented in this section, and the reader is referred to both Chapter 11 of the RIA and NHTSA's FEIS Chapters 3, 4 and 5 for complete sets of these analyses. In this section, Method A is presented for the final standards (*i.e.*, Alternative 3—the agencies' preferred alternative), relative to both the dynamic baseline (Alternative 1b) and the flat baseline (Alternative 1a). Method B is presented for the final standards, relative only to the flat baseline.

Because reducing fuel consumption also affects emissions that occur as a result of fuel production and distribution (including renewable fuels), the agencies also calculated those "upstream" changes using the "downstream" fuel consumption reductions predicted by the CAFE model (in "Method A") and the MOVES model (in "Method B"). As described in Section VI, Method A uses the CAFE model to estimate vehicular fuel consumption and emissions impacts only for HD pickups and vans and to calculate upstream impacts. For vocational vehicles and combination tractor-trailers, both Method A and Method B use the same upstream tools originally created for the Renewable Fuel Standard 2 (RFS2) rulemaking

analysis,⁵³⁷ used in the LD GHG rulemakings,⁵³⁸ HD GHG Phase 1,⁵³⁹ and updated for the current analysis. The estimate of emissions associated with production and distribution of gasoline and diesel from crude oil is based on emission factors in the "Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation" model (GREET) developed by DOE's Argonne National Lab. In some cases, the GREET values were modified or updated by the agencies to be consistent with the National Emission Inventory (NEI) and emission factors from MOVES. Method B uses the same tool described above to estimate the upstream impacts for HD pickups and vans. For additional details, see Chapter 5 of the RIA. The upstream tool used for the Method B can be found in the docket.⁵⁴⁰ As noted in Section VI above, these analyses corroborate each other's results.

The agencies analyzed the anticipated emissions impacts of the final rules on carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), and hydrofluorocarbons (HFCs) for a number of calendar years (for purposes of the discussion in these final rules, only 2025, 2040 and 2050 will be shown) by comparing to both reference cases.⁵⁴¹ Additional runs were performed for just three of the greenhouse gases (CO₂, CH₄, and N₂O) and for fuel consumption for every calendar year from 2016 to 2050, inclusive, which fed the economy-wide modeling, monetized greenhouse gas benefits estimation, and climate impacts analyses, discussed in sections below.⁵⁴²

⁵³⁹ Greenhouse Gas Emission Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles (76 FR 57106, September 15, 2011).

⁵⁴⁰ Memorandum to the Docket "Upstream Emissions Modeling Files for HDGHG Phase 2 FRM" Docket No. EPA-HQ-OAR-2016. July 2016.

⁵⁴¹ The emissions impacts of the final rules on non-GHGs, including air toxics, were also estimated using MOVES. See Section VIII of the Preamble for more information.

⁵⁴² The CAFE model estimates, among other things, manufacturers' potential multiyear planning decisions within the context of an estimated year-by-year product cadence (*i.e.*, schedule for redesigning and freshening vehicles). The model was allowed to deploy technology in earlier model years in the analysis in order to account for the potential that manufacturers might take anticipatory actions in model years preceding those covered by today's rules.

⁵³⁶ Memorandum to the Docket "Runspects, Model Inputs, MOVES Code and Database for HD GHG Phase 2 FRM Emissions Modeling" Docket No. EPA-HQ-OAR-2016. July 2016.

B. Analysis of Fuel Consumption and GHG Emissions Impacts Resulting From Final Standards

The following sections describe the model inputs and assumptions for both the flat and dynamic reference cases and the control case representing the agencies' final fuel efficiency and GHG standards. The details of all the MOVES runs and input data tables, as well as the MOVES code and database, can be found in the docket.⁵⁴³ See Section VI.C for the discussion of the model inputs and assumptions for the analysis of the HD pickups and vans using DOT's CAFE Model.

(1) Model Inputs and Assumptions for the Flat Reference Case

The flat reference case (identified as Alternative 1a in Section X), includes the impact of Phase 1, but assumes that fuel efficiency and GHG emission standards are not improved beyond the required 2018 model year levels. Alternative 1a functions as one of the baselines against which the impacts of the final standards can be evaluated. The MOVES2014a default road load parameters and energy rates were used for the vocational vehicles and HD pickups and vans for this alternative because we assumed no market-driven improvements in fuel efficiency. The tractor-trailer road load parameters were changed from the MOVES2014a default values to account for projected improvements in the efficiency of the box trailers pulled by combination tractors due to increased penetration of aerodynamic technologies and low rolling resistance tires attributed to both

EPA's SmartWay Transport Partnership and California Air Resources Board's Tractor-Trailer Greenhouse Gas regulation, as described in Section IV of the Preamble. We maintained the same road load inputs for tractor-trailers for 2018 and beyond. The flat reference case assumed the growth in vehicle populations and miles traveled based on the relative annual VMT growth from AEO2015 Final Release for model years 2014 and later.⁵⁴⁴

(2) Model Inputs and Assumptions for the Dynamic Reference Case

The dynamic reference case (identified as Alternative 1b in Section X) also includes the impact of Phase 1 and generally assumes that fuel efficiency and GHG emission standards are not improved beyond the required 2018 model year levels. However, for this case, the agencies assume market forces will lead to additional fuel efficiency improvements for HD pickups and vans and tractor-trailers. These additional assumed improvements are described in Section X of the Preamble. No additional fuel efficiency improvements due to market forces were assumed for vocational vehicles. For HD pickups and vans, the agencies applied the CAFE model using the input assumption that manufacturers having achieved compliance with Phase 1 standards will continue to apply technologies for which increased purchase costs will be "paid back" through corresponding fuel savings within the first six months of vehicle operation. The agencies conducted the

MOVES analysis of this case in the same manner as for the flat reference case.

(3) Model Inputs and Assumptions for "Control" Case

(a) Vocational Vehicles and Tractor-Trailers

The "control" case represents the agencies' final fuel efficiency and GHG standards. The agencies developed additional user input data for MOVES runs to estimate the control case inventories. The inputs to MOVES for the control case account for improvements of engine and vehicle efficiency in vocational vehicles and combination tractor-trailers. The agencies used the percent reduction in aerodynamic drag and tire rolling resistance coefficients and absolute changes in average total running weight (gross combined weight) expected from the final rules to develop the road load inputs for the control case, based on the GEM analysis. The agencies developed energy inputs for the control case runs using the percent reduction in CO₂ emissions expected from the powertrain and other vehicle technologies not accounted for in the aerodynamic drag and tire rolling resistance in the final rules.

Table VII–1 and Table VII–2 describe the improvements in engine and vehicle efficiency from the final rules for each affected model year for vocational vehicles and combination tractor-trailers that were input into MOVES for estimating the control case emissions inventories. Additional details regarding the MOVES inputs are included in Chapter 5 of the RIA.

TABLE VII–1—ESTIMATED REDUCTIONS IN ENERGY RATES FOR THE FINAL STANDARDS

Vehicle type	Fuel	Model years	Reduction from flat baseline (%)
Long-haul Tractor-Trailers and HHD Vocational	Diesel	2018–2020	1.0
		2021–2023	7.9
		2024–2026	12.4
		2027+	16.3

		2027+	15.0
Single-Frame Vocational ⁵⁴⁵	Diesel	2021–2023	7.8
		2024–2026	12.3
		2027+	16.0

⁵⁴³ Memorandum to the Docket "Runspects, Model Inputs, MOVES Code and Database for HD GHG Phase 2 FRM Emissions Modeling" Docket No. EPA–HQ–OAR–2016. July 2016.

⁵⁴⁴ Annual Energy Outlook 2015. <http://www.eia.gov/forecasts/archive/aeo15/> (last accessed May 27, 2016).

⁵⁴⁵ Vocational vehicles modeled in MOVES include heavy heavy-duty, medium heavy-duty, and light heavy-duty vehicles. However, for light heavy-duty vocational vehicles, class 2b and 3 vehicles are not included in the inventories for the vocational sector. Instead, all vocational vehicles with GVWR of less than 14,000 lbs. were modeled

using the energy rate reductions described below for HD pickup trucks and vans. In practice, many manufacturers of these vehicles choose to average the lightest vocational vehicles into chassis-certified families (*i.e.*, heavy-duty pickups and vans).

TABLE VII-1—ESTIMATED REDUCTIONS IN ENERGY RATES FOR THE FINAL STANDARDS—Continued

Vehicle type	Fuel	Model years	Reduction from flat base-line (%)
Urban Bus	Gasoline	2021–2023	6.9
		2024–2026	9.8
		2027+	13.3
	Diesel and CNG	2021–2023	7.0
		2024–2026	11.8
		2027+	14.4

TABLE VII-2—ESTIMATED REDUCTIONS IN ROAD LOAD FACTORS FOR THE FINAL STANDARDS

Vehicle type	Model years	Reduction in tire rolling resistance coefficient (%)	Reduction in aerodynamic drag coefficient (%)	Weight reduction (lb) ^a
Combination Long-haul Tractor-Trailers	2018–2020	6.1	5.6	– 140
	2021–2023	13.3	12.5	– 199
	2024–2026	16.3	19.3	– 294

	2024–2026	20.8	0	0
	2027+	24.7	0	0

Note:

^a Negative weight reductions reflect an expected weight increase as a byproduct of other vehicle and engine improvements as described in Chapter 5 of the RIA.

In addition, the CO₂ standard for tractors, reflecting the use of idle reduction technologies such as diesel-

powered auxiliary power units (APUs) and battery-powered APUs, as discussed in Section III.D of the Preamble, was

included in the modeling for the long-haul combination tractor-trailers, as shown below in Table VII-3.

TABLE VII-3—ASSUMED APU USE DURING EXTENDED IDLING FOR COMBINATION LONG-HAUL TRACTOR-TRAILERS ^a

Vehicle type	Model year	Diesel APU Penetration (%)	Battery APU Penetration (%)
Combination Long-Haul Trucks	2010–2020	9	0
	2021–2023	30	10
	2024–2026	40	10
	2027+	40	15

Note:

⁵⁴⁶ Vocational tractors are included in the short-haul tractor segment.

^aOther idle reduction technologies (such as automatic engine shutdown, fuel operated heaters, and stop-start systems) were modeled as part of the energy rates.

To account for the potential increase in vehicle use expected to result from improvements in fuel efficiency for vocational vehicles and combination tractor-trailers due to the final rules (also known as the “rebound effect” and described in more detail in Section IX.E of the Preamble), the control case assumed an increase in VMT from the reference levels by 0.30 percent for the vocational vehicles and 0.75 percent for the combination tractor-trailers.⁵⁴⁷

(b) Heavy-Duty Pickups and Vans

As explained above and as also discussed in the RIA, the agencies used both DOT’s CAFE model and EPA’s MOVES model, for Method A and B, respectively, to project fuel consumption and GHG emissions impacts resulting from these standards for HD pickups and vans, including downstream vehicular emissions as well as emissions from upstream processes related to fuel production, distribution, and delivery.

(i) Method A for HD Pickups and Vans

For Method A, the agencies used the CAFE model which applies fuel properties (density and carbon content) to estimated fuel consumption in order to calculate vehicular CO₂ emissions, applies per-mile emission factors from MOVES to estimated VMT (for each regulatory alternative, adjusted to account for the rebound effect) in order to calculate vehicular CH₄ and N₂O emissions (as well, as discussed below, of non-GHG pollutants), and applies per-gallon upstream emission factors from GREET in order to calculate upstream GHG (and non-GHG) emissions.

As discussed above in Section VI, the standards for HD pickups and vans increase in stringency by 2.5 percent annually during model years 2021–2027. The standards define targets specific to each vehicle model, but no

individual vehicle is required to meet its target; instead, the production-weighted averages of the vehicle-specific targets define average fuel consumption and CO₂ emission rates that a given manufacturer’s overall fleet of produced vehicles is required to achieve as a whole. The standards are specified separately for gasoline and diesel vehicles, and vary with work factor. Both the NPRM and today’s analysis assume that some application of mass reduction could enable increased work factor in cases where manufacturers increase a vehicle’s rated payload and/or towing capacity without a change to GVWR and GCWR, but there are other ways manufacturers may change work factor which the analysis does not capture. Average required levels will depend on the future mix of vehicles and the work factors of the vehicles produced for sale in the U.S. Since these can only be estimated at this time, average required and achieved fuel consumption and CO₂ emission rates are subject to uncertainty. Between the NPRM and the issuance of today’s final rules, the agencies updated the market forecast (and other inputs) used to analyze HD pickup and van standards, and doing so leads to different estimates of required and achieved fuel consumption and CO₂ emission rates (as well as different estimates of impacts, costs, and benefits).

The following four tables present stringency increases and estimated required and achieved fuel consumption and CO₂ emission rates for the two No Action Alternatives (Alternative 1a and 1b) and the standards defining the final program. Stringency increases are shown relative to standards applicable in model year 2018 (and through model year 2020). As mathematical functions, the standards themselves are not subject to uncertainty. By 2027, they are 16.2 percent more stringent (*i.e.*, lower) than those applicable during 2018–2020.

NHTSA estimates that, by model 2027, these standards could reduce average required fuel consumption and CO₂ emission rates to about 4.88 gallons/100 miles and about 4 grams/mile, respectively. NHTSA further estimates that average achieved fuel consumption and CO₂ emission rates could correspondingly be reduced to about the same levels. If, as represented by Alternative 1b, manufacturers will, even absent today’s standards, voluntarily make improvements that pay back within six months, these model year 2027 levels are about 12 percent lower than the agencies estimate could be achieved under the Phase 1 standards defining the No Action Alternative. If, as represented by Alternative 1a, manufacturers will, absent today’s standards, only apply technology as required to achieve compliance, these model year 2027 levels are about 13 percent lower than the agencies estimate could be achieved under the Phase 1 standards. As indicated below, the agencies estimate that these improvements in fuel consumption and CO₂ emission rates will build from model year to model year, beginning as soon as model year 2017 (insofar as manufacturers may make anticipatory improvements if warranted given planned product cadence).

The NPRM analysis suggested that both the achieved and required fuel consumption and CO₂ reductions would be larger than the current analysis suggests. The NPRM suggested that achieved reductions would be 13.5 and 15 percent, for the dynamic and flat baselines, respectively. The erosion of the standards and fuel consumption reductions can be attributed to the increased work factor of the 2015 fleet relative to the 2014 fleet. Section 6 discusses in more detail the changes in the distribution of work factor for key market players from the MY 2014 to the MY 2015 fleet.

⁵⁴⁷ Memorandum to the Docket “VMT Rebound Inputs to MOVES for HDGHG2 Phase 2 FRM” Docket No. EPA–HQ–OAR–2016, July 2016.

* Absent further action, standards assumed to continue unchanged after model year 2027.

** Increased work factor for some vehicles produces a slight increase in the average required CO₂ emission rate.

While the above tables show the agencies' estimates of average fuel consumption and CO₂ emission rates manufacturers of pickups and vans might achieve under today's standards, total U.S. fuel consumption and GHG emissions from HD pickups and vans will also depend on how many of these vehicles are produced, and how they are operated over their useful lives. Relevant to estimating these outcomes, the CAFE model applies vintage-specific estimates of vehicle survival and

mileage accumulation, and adjusts the latter to account for the rebound effect. This impact of the rebound effect is specific to each model year (and, underlying, to each vehicle model in each model year), varying with changes in achieved fuel consumption rates.

(ii) Method B for HD Pickups and Vans

For Method B, the MOVES model was used to estimate fuel consumption and GHG emissions for HD pickups and vans. MOVES evaluated these standards

for HD pickup trucks and vans in terms of grams of CO₂ per mile or gallons of fuel per 100 miles. Since nearly all HD pickup trucks and vans are certified on a chassis dynamometer, the CO₂ reductions for these vehicles were not represented as engine and road load reduction components, but rather as total vehicle CO₂ reductions. The control case for HD pickups and vans assumed an increase in VMT from the reference levels of 1.08 percent.⁵⁴⁸

⁵⁴⁸ Memorandum to the Docket "VMT Rebound Inputs to MOVES for HDGHG2 Phase 2 FRM" Docket No. EPA-HQ-OAR-2016, July 2016.

TABLE VII–8—ESTIMATED TOTAL VEHICLE CO₂ REDUCTIONS FOR THE FINAL STANDARDS AND IN-USE EMISSIONS FOR HD PICKUP TRUCKS AND VANS IN METHOD B^a

Vehicle type	Fuel	Model year	CO ₂ reduction from flat baseline (%)

Note:

^aFor an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

C. What are the projected reductions in fuel consumption and GHG emissions?

NHTSA and EPA expect significant reductions in GHG emissions and fuel consumption from the final rules—fuel consumption reductions from more efficient vehicles, emission reductions from both downstream (tailpipe) and upstream (fuel production and distribution) sources, and reduction in HFC emissions from the air conditioning leakage standards (see Section V.B.(2)(c)). The following subsections summarize two different analyses of the annual GHG emissions and fuel consumption reductions expected from these final rules, as well as the reductions in GHG emissions and fuel consumption expected over the lifetime of each heavy-duty vehicle category. Section VII.C.(1) shows the impacts of the final rules on fuel consumption and GHG emissions, using the MOVES model for tractor-trailers and vocational vehicles and the DOT's CAFE model for HD pickups and vans (Method A), relative to two different

reference cases—flat and dynamic. Section VII.C.2 shows the impacts of the final standards, relative to the flat reference case only, using the MOVES model for all heavy-duty vehicle categories. NHTSA also analyzes these impacts resulting from the final rules and reasonable alternatives in Chapters 3, 4 and 5 of its FEIS.

(1) Impacts of the Final Rules Using Analysis Method A

(a) Calendar Year Analysis

(i) Downstream (Tailpipe) Emissions Projections

As described in Section VII.A, for the analysis using Method A, the agencies used MOVES to estimate downstream GHG inventories from the final rules for vocational vehicles and tractor-trailers. For HD pickups and vans, DOT's CAFE model was used.

The following two tables summarize the agencies' estimates of HD pickup and van fuel consumption and GHG emissions under the current standards defining the No-Action and final

program, respectively, using Method A. Table VII–9 shows results assuming manufacturers will voluntarily make improvements that pay back within six months (*i.e.*, Alternative 1b). Table VII–10 shows results assuming manufacturers will only make improvements as needed to achieve compliance with standards (*i.e.*, Alternative 1a). While underlying calculations are all performed for each calendar year during each vehicle's useful life, presentation of outcomes on a model year basis aligns more clearly with consideration of cost impacts in each model year, and with consideration of standards specified on a model year basis. In addition, Method A analyzes manufacturers' potential responses to HD pickup and van standards on a model year basis through 2030, and any longer-term costs presented in today's notice represent extrapolation of these results absent any underlying analysis of longer-term technology prospects and manufacturers' longer-term product offerings.

(2) Impacts of the Final Rules Using Analysis Method B

(a) Calendar Year Analysis

(i) Downstream (Tailpipe) Emissions Projections

As described in Section VII.A., Method B used MOVES to estimate downstream GHG inventories from the final rules, relative to Alternative 1a, for all heavy-duty vehicle categories (including the engines associated with tractor-trailer combinations and vocational vehicles). The agencies expect reductions in CO₂ emissions from all heavy-duty vehicle categories due to engine and vehicle improvements. We expect N₂O

emissions to increase very slightly because of a rebound in vehicle miles traveled (VMT). However, since N₂O is produced as a byproduct of fuel combustion, the increase in N₂O emissions is expected to be more than offset by the improvements in fuel efficiency from the final rules.⁵⁴⁹ We expect methane emissions to decrease primarily due to reduced refueling from improved fuel efficiency and the differences in hydrocarbon emission characteristics between on-road diesel engines and APUs. The amount of methane emitted as a fraction of total hydrocarbons is expected to be less for APUs than for on-road diesel engines during extended idling. Overall, the downstream GHG emissions will be

reduced significantly and are described in the following subsections.

Fuel consumption is calculated from the MOVES output of total energy consumption converted using the fuel heating values assumed in the Renewable Fuels Standard rulemaking⁵⁵⁰ and in MOVES.⁵⁵¹

Table VII–20 shows the impacts on downstream GHG emissions and fuel savings in 2025, 2040 and 2050, relative to Alternative 1a, for the final program.

Table VII–21 shows the estimated fuel savings from the final program in 2025, 2040, and 2050, relative to Alternative 1a. The results from the comparable analyses relative to Alternative 1b are presented in Section VII.C.(1).

2050	13.0	21.0	1.9	14.4

Note:

^a For an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

(ii) Upstream (Fuel Production and Distribution) Emissions Projections

The upstream GHG emission reductions associated with the production and distribution of gasoline and diesel from crude oil include the domestic emission reductions only. Additionally, since this rulemaking is not expected to impact biofuel volumes mandated by the annual Renewable Fuel Standards (RFS) regulations⁵⁵², the impacts on upstream emissions from

changes in biofuel feedstock (*i.e.*, agricultural sources such as fertilizer, fugitive dust, and livestock) are not shown. In other words, we attribute decreased fuel consumption from this program to petroleum-based fuels only, while assuming no net effect on volumes of renewable fuels. We used this approach because annual renewable fuel volumes are mandated independently from this rulemaking under RFS. As a consequence, it is not possible to conclude whether the

decreasing petroleum consumption projected here would increase the fraction of the U.S. fuel supply that is made up by renewable fuels (if RFS volumes remained constant), or whether future renewable fuel volume mandates would decrease in proportion to the decreased petroleum consumption projected here.

As background, EPA sets annual renewable fuel volume mandates through a separate RFS notice-and-comment rulemaking process, and the

⁵⁴⁹ MOVES is not capable of modeling the changes in exhaust N₂O emissions from the improvements in fuel efficiency. Due to this limitation, a conservative approach was taken to only model the VMT rebound in estimating the emissions impact on N₂O from the final rules, resulting in a slight increase in downstream N₂O inventory.

⁵⁵⁰ Renewable Fuels Standards assumptions of 115,000 BTU/gallon gasoline (E0) and 76,330 BTU/gallon ethanol (E100) were weighted 90 percent and 10 percent, respectively, for E10 and 85 percent and 15 percent, respectively, for E15 and converted to kJ at 1.055 kJ/BTU. The conversion factors are 117,245 kJ/gallon for gasoline blended with ten percent ethanol (E10) and 115,205 kJ/gallon for gasoline blended with fifteen percent ethanol (E15).

⁵⁵¹ The conversion factor for diesel is 138,451 kJ/gallon. See MOVES2004 Energy and Emission Inputs. EPA420–P–05–003, March 2005. <http://www3.epa.gov/otaq/models/ngm/420p05003.pdf> (last accessed Mar 15, 2016).

⁵⁵² U.S. EPA. 2014 Standards for the Renewable Fuel Standard Program. 40 CFR part 80. EPA–HQ–OAR–2013–0479; FRL–9900–90–OAR, RIN 2060–AR76.

final volumes are based on EIA projections, EPA's own market assessment, and information obtained from the RFS notice and comment process. Also, RFS standards are nested within each other, which means that a fuel with a higher GHG reduction

threshold can be used to meet the standards for a lower GHG reduction threshold. This creates additional uncertainty in projecting this rule's net effect on future annual RFS standards. In conclusion, the impacts of this rulemaking on annual renewable fuel volume mandates are difficult to project

at the present time. However, since it is not centrally relevant to the analysis for this rulemaking, we have not included any impacts on renewable fuel volumes in this analysis. The upstream GHG emission reductions of the final program can be found in Table VII–22.

(iii) HFC Emissions Projections

The projected HFC emission reductions due to the HD Phase 2 air conditioning leakage standards for vocational vehicles are 86,735 metric tons of CO₂eq in 2025, 256,061 metric tons of CO₂eq in 2040, and 314,930

metric tons CO₂eq in 2050. See Chapter 5 of the RIA for additional details on calculations of HFC emissions.

(iv) Total (Downstream + Upstream + HFC) Emissions Projections

Table VII–23 combines the impacts of the final program from downstream

(Table VII–20), upstream (Table VII–22), and HFC to summarize the total GHG reductions in calendar years 2025, 2040 and 2050, relative to Alternative 1a.

TABLE VII–23—ANNUAL TOTAL GHG EMISSIONS IMPACTS IN CALENDAR YEARS 2025, 2040 AND 2050—FINAL PROGRAM VS. ALT 1a USING ANALYSIS METHOD B^a

^bHFC represents HFC emission reductions and percent change from the vocational vehicle category only.

(b) Model Year Lifetime Analysis

In addition to the annual GHG emissions and fuel consumption reductions expected from the final rules, we estimated the combined

(downstream and upstream) GHG and fuel consumption impacts for the lifetime of the impacted vehicles sold in the regulatory timeframe. Table VII–24 shows the fleet-wide GHG reductions and fuel savings from the final program,

relative to Alternative 1a, through the lifetime of heavy-duty vehicles.⁵⁵³ For the lifetime GHG reductions and fuel savings by vehicle categories, see Chapter 5 of the RIA.

TABLE VII–24—LIFETIME GHG REDUCTIONS AND FUEL SAVINGS USING ANALYSIS METHOD B—SUMMARY FOR MODEL YEARS 2018–2029^a

Model years	Final program (Alternative 3)
No-action alternative (baseline)	1a (Flat)
Fuel Savings (Billion Gallons)	82.2
Total GHG Reductions (MMT CO ₂ eq)	1,097.6
Downstream (MMT CO ₂ eq)	819.2
Upstream (MMT CO ₂ eq)	278.4

Note:

⁵⁵³ A lifetime of 30 years is assumed in MOVES.

D. Climate Impacts and Indicators

(1) Climate Change Impacts From GHG Emissions

The impact of GHG emissions on the climate has been reviewed in the 2009 Endangerment and Cause or Contribute Findings for Greenhouse Gases under Section 202(a) of the Clean Air Act, the 2012–2016 light-duty vehicle rulemaking, the 2014–2018 heavy-duty vehicle GHG and fuel efficiency rulemaking, the 2017–2025 light-duty vehicle rulemaking, and the standards for new electricity utility generating units. See 74 FR 66496; 75 FR 25491; 76 FR 57294; 77 FR 62894; 79 FR 1456–1459; 80 FR 64662. This section briefly discusses again some of the climate impact of EPA's actions in context of transportation emissions. NHTSA has analyzed the climate impacts of its specific actions (*i.e.*, excluding EPA's HFC regulatory provisions) as well as reasonable alternatives in its DEIS that accompanies this final rules. DOT has considered the potential climate impacts documented in the DEIS as part of the rulemaking process.

Once emitted, GHGs that are the subject of this regulation can remain in the atmosphere for decades to millennia, meaning that (1) their concentrations become well-mixed throughout the global atmosphere regardless of emission origin, and (2) their effects on climate are long lasting. GHG emissions come mainly from the combustion of fossil fuels (coal, oil, and gas), with additional contributions from the clearing of forests, agricultural activities, cement production, and some industrial activities. Transportation activities, in aggregate, were the second largest contributor to total U.S. GHG emissions in 2010 (27 percent of total emissions).⁵⁵⁴

The EPA Administrator relied on thorough and peer-reviewed assessments of climate change science prepared by the Intergovernmental Panel on Climate Change ("IPCC"), the United States Global Change Research Program ("USGCRP"), and the National Research Council of the National Academies ("NRC")⁵⁵⁵ as the primary

scientific and technical basis for the Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act (74 FR 66496, December 15, 2009). These assessments comprehensively address the scientific issues the EPA Administrator had to examine, providing her data and information on a wide range of issues pertinent to the Endangerment Finding. These assessments have been rigorously reviewed by the expert community, and also by United States government agencies and scientists, including by EPA itself.

Based on these assessments, the EPA Administrator determined that the emissions from new motor vehicles and engines contribute to elevated concentrations of greenhouse gases; that these greenhouse gases cause warming; that the recent warming has been attributed to the increase in greenhouse gases; and that warming of the climate endangers the public health and welfare of current and future generations. See *Coalition for Responsible Regulation v. EPA*, 684 F. 3d 102, 121 (D.C. Cir. 2012) (upholding all of EPA's findings and stating "EPA had before it substantial record evidence that anthropogenic emissions of greenhouse gases 'very likely' caused warming of the climate over the last several decades. EPA further had evidence of current and future effects of this warming on public health and welfare. Relying again upon substantial scientific evidence, EPA determined that anthropogenically induced climate change threatens both public health and public welfare. It found that extreme weather events, changes in air quality, increases in food- and water-borne pathogens, and increases in temperatures are likely to have adverse health effects. The record also supports EPA's conclusion that climate change endangers human welfare by creating risk to food production and agriculture, forestry, energy, infrastructure, ecosystems, and wildlife. Substantial evidence further supported EPA's conclusion that the warming resulting from the greenhouse gas emissions could be expected to create risks to water resources and in general to coastal areas as a result of expected increase in sea level.")

A number of major peer-reviewed scientific assessments have been released since the administrative record

concerning the Endangerment Finding closed following EPA's 2010 Reconsideration Denial.⁵⁵⁶ These assessments include the "Special Report on Managing the Risks of Extreme Events and Disasters to Advance Climate Change Adaptation"⁵⁵⁷, the 2013–14 Fifth Assessment Report (AR5),⁵⁵⁸ the 2014 National Climate Assessment report,⁵⁵⁹ the "Ocean Acidification: A National Strategy to Meet the Challenges of a Changing Ocean,"⁵⁶⁰ "Report on Climate Stabilization Targets: Emissions, Concentrations, and Impacts over Decades to Millennia,"⁵⁶¹ "National Security Implications for U.S. Naval Forces" (National Security Implications),⁵⁶² "Understanding Earth's Deep Past: Lessons for Our Climate Future,"⁵⁶³ "Sea Level Rise for

the Coasts of California, Oregon, and Washington: Past, Present, and Future,”⁵⁶⁴ “Climate and Social Stress: Implications for Security Analysis,”⁵⁶⁵ and “Abrupt Impacts of Climate Change” (Abrupt Impacts) assessments.⁵⁶⁶

EPA has reviewed these assessments and finds that, in general, the improved understanding of the climate system they present is consistent with the assessments underlying the 2009 Endangerment Finding.

The most recent assessments released were the IPCC AR5 assessments between September 2013 and April 2014, the NRC Abrupt Impacts assessment in December of 2013, and the U.S. National Climate Assessment in May of 2014. The NRC Abrupt Impacts report examines the potential for tipping points, thresholds beyond which major and rapid changes occur in the Earth's climate system or other systems impacted by the climate. The Abrupt Impacts report did find less cause for concern than some previous assessments regarding some abrupt events within the next century, such as disruption of the Atlantic Meridional Overturning Circulation (AMOC) and sudden releases of high-latitude methane from hydrates and permafrost, but found that the potential for abrupt changes in ecosystems, weather and climate extremes, and groundwater supplies critical for agriculture now seem more likely, severe, and imminent. The assessment found that some abrupt changes were already underway (Arctic sea ice retreat and increases in extinction risk due to the speed of climate change) but cautioned that even abrupt changes such as the AMOC disruption that are not expected in this century can have severe impacts when they happen.

The IPCC AR5 assessments are also generally consistent with the underlying science supporting the 2009 Endangerment Finding. For example, confidence in attributing recent warming to human causes has increased: The IPCC stated that it is extremely likely (≥ 95 percent confidence) that human influences have

been the dominant cause of recent warming. Moreover, the IPCC found that the last 30 years were likely (≤ 66 percent confidence) the warmest 30 year period in the Northern Hemisphere of the past 1400 years, that the rate of ice loss of worldwide glaciers and the Greenland and Antarctic ice sheets has likely increased, that there is medium confidence that the recent summer sea ice retreat in the Arctic is larger than it has been in 1450 years, and that concentrations of carbon dioxide and several other of the major greenhouse gases are higher than they have been in at least 800,000 years. Climate-change induced impacts have been observed in changing precipitation patterns, melting snow and ice, species migration, negative impacts on crops, increased heat and decreased cold mortality, and altered ranges for water-borne illnesses and disease vectors. Additional risks from future changes include death, injury, and disrupted livelihoods in coastal zones and regions vulnerable to inland flooding, food insecurity linked to warming, drought, and flooding, especially for poor populations, reduced access to drinking and irrigation water for those with minimal capital in semi-arid regions, and decreased biodiversity in marine ecosystems, especially in the Arctic and tropics, with implications for coastal livelihoods. The IPCC determined that “[c]ontinued emissions of greenhouse gases will cause further warming and changes in all components of the climate system. Limiting climate change will require substantial and sustained reductions of greenhouse gases emissions.”

Finally, the recently released National Climate Assessment stated, “Climate change is already affecting the American people in far reaching ways. Certain types of extreme weather events with links to climate change have become more frequent and/or intense, including prolonged periods of heat, heavy downpours, and, in some regions, floods and droughts. In addition, warming is causing sea level to rise and glaciers and Arctic sea ice to melt, and oceans are becoming more acidic as they absorb carbon dioxide. These and other aspects of climate change are disrupting people's lives and damaging some sectors of our economy.”

Assessments from these bodies represent the current state of knowledge, comprehensively cover and synthesize thousands of individual studies to obtain the majority conclusions from the body of scientific literature and undergo a rigorous and exacting standard of review by the peer expert community and U.S. government.

Based on modeling analysis performed by the agencies, reductions in CO₂ and other GHG emissions associated with these final rules will affect future climate change. Since GHGs are well-mixed in the atmosphere and have long atmospheric lifetimes, changes in GHG emissions will affect atmospheric concentrations of greenhouse gases and future climate for decades to millennia, depending on the gas. This section provides estimates of the projected change in atmospheric CO₂ concentrations based on the emission reductions estimated for these final rules, compared to the reference case. In addition, this section analyzes the response to the changes in GHG concentrations of the following climate-related variables: Global mean temperature, sea level rise, and ocean pH.

(2) Projected Change in Atmospheric CO₂ Concentrations, Global Mean Surface Temperature and Sea Level Rise

To assess the impact of the emissions reductions from the final rules, EPA estimated changes in projected atmospheric CO₂ concentrations, global mean surface temperature and sea-level rise to 2100 using the GCAM (Global Change Assessment Model, formerly MiniCAM), integrated assessment model⁵⁶⁷ coupled with the MAGICC (Model for the Assessment of Greenhouse-gas Induced Climate Change) simple climate model.⁵⁶⁸ GCAM was used to create the globally and temporally consistent set of climate relevant emissions required for running MAGICC. MAGICC was then used to estimate the projected change in relevant climate variables over time. Given the magnitude of the estimated

⁵⁶⁷ GCAM is a long-term, global integrated assessment model of energy, economy, agriculture and land use that considers the sources of emissions of a suite of greenhouse gases (GHG's), emitted in 14 globally disaggregated regions, the fate of emissions to the atmosphere, and the consequences of changing concentrations of greenhouse related gases for climate change. GCAM begins with a representation of demographic and economic developments in each region and combines these with assumptions about technology development to describe an internally consistent representation of energy, agriculture, land-use, and economic developments that in turn shape global emissions.

⁵⁶⁸ MAGICC consists of a suite of coupled gas-cycle, climate and ice-melt models integrated into a single framework. The framework allows the user to determine changes in greenhouse-gas concentrations, global-mean surface air temperature and sea-level resulting from anthropogenic emissions of carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), reactive gases (CO, NO_x, VOCs), the halocarbons (e.g. HCFCs, HFCs, PFCs) and sulfur dioxide (SO₂). MAGICC emulates the global-mean temperature responses of more sophisticated coupled Atmosphere/Ocean General Circulation Models (AOGCMs) with high accuracy.

⁵⁶⁶ National Research Council (NRC). 2013. Abrupt Impacts of Climate Change: Anticipating Surprises. National Academies Press. Washington, DC.

emissions reductions associated with these rules, a simple climate model such as MAGICC is appropriate for estimating the atmospheric and climate response.

The analysis projects that the final rules will reduce atmospheric concentrations of CO₂, global climate warming, ocean acidification, and sea level rise relative to the reference case. Although the projected reductions and improvements are small in comparison to the total projected climate change, they are quantifiable, directionally consistent, and will contribute to reducing the risks associated with climate change. Climate change is a global phenomenon, and EPA

recognizes that this one national action alone will not prevent it; EPA notes this would be true for any given GHG mitigation action when taken alone or when considered in isolation. EPA also notes that a substantial portion of CO₂ emitted into the atmosphere is not removed by natural processes for millennia, and therefore each unit of CO₂ not emitted into the atmosphere due to this rules avoids essentially permanent climate change on centennial time scales.

EPA determines that the projected reductions in atmospheric CO₂, global mean temperature, sea level rise, and ocean pH are meaningful in the context

of this action. The results of the analysis, summarized in Table VII–25, demonstrate that relative to the reference case, by 2100 projected atmospheric CO₂ concentrations are estimated to be reduced by 1.2 to 1.3 part per million by volume (ppmv), global mean temperature is estimated to be reduced by 0.0027 to 0.0065 °C, and sea-level rise is projected to be reduced by approximately 0.026 to 0.058 cm, based on a range of climate sensitivities (described below). Details about this modeling analysis can be found in the RIA Chapter 6.3.

TABLE VII–25—IMPACT OF GHG EMISSIONS REDUCTIONS ON PROJECTED CHANGES IN GLOBAL CLIMATE ASSOCIATED WITH PHASE 2 STANDARDS FOR MY 2018–2024

[Based on a range of climate sensitivities from 1.5–6 °C]

Variable	Units	Year	Projected change
Atmospheric CO ₂ Concentration	ppmv	2100	– 1.2 to – 1.3
Global Mean Surface Temperature	°C	2100	– 0.0027 to – 0.0065
Sea Level Rise	cm	2100	– 0.026 to – 0.058
Ocean pH	pH units	2100	+0.0006 ^a

Note:

^a The value for projected change in ocean pH is based on a climate sensitivity of 3.0.

The projected reductions are small relative to the change in temperature (1.8–4.8 °C), CO₂ concentration (404 to 470 ppm), sea level rise (23–56 cm), and ocean acidity (– 0.30 pH units) from 1990 to 2100 from the MAGICC simulations for the GCAM reference case. However, this is to be expected given the magnitude of emissions reductions expected from the program in the context of global emissions. Moreover, these effects are occurring everywhere around the globe, so benefits that appear to be marginal for any one location, such as a reduction in sea level rise of half a millimeter, can be sizable when the effects are summed along thousands of miles of coastline. This uncertainty range does not include the effects of uncertainty in future emissions. It should also be noted that the calculations in MAGICC do not include the possible effects of accelerated ice flow in Greenland and/or Antarctica: estimates of sea level rise from the recent NRC, IPCC, and NCA assessments range from 26 cm to 2 meters depending on the emissions scenario, the processes included, and the likelihood range assessed; inclusion of these effects would lead to correspondingly larger benefits of mitigation. Further discussion of EPA's modeling analysis is found in the RIA, Chapter 6.3.

Based on the projected atmospheric CO₂ concentration reductions resulting

from these final rules, EPA calculates an increase in ocean pH of 0.0006 pH units in 2100 relative to the baseline case (this is a reduction in the expected acidification of the ocean of a decrease of 0.3 pH units from 1990 to 2100 in the baseline case). Thus, this analysis indicates the projected decrease in atmospheric CO₂ concentrations from the Phase 2 standards will result in an increase in ocean pH (*i.e.*, a reduction in the expected acidification of the ocean in the reference case). A more detailed discussion of the modeling analysis associated with ocean pH is provided in the RIA, Chapter 6.3.

The 2011 NRC assessment on “Climate Stabilization Targets: Emissions, Concentrations, and Impacts over Decades to Millennia” determined how a number of climate impacts—such as heaviest daily rainfalls, crop yields, and Arctic sea ice extent—would change with a temperature change of 1 degree Celsius (C) of warming. These relationships of impacts with temperature change could be combined with the calculated reductions in warming in Table VII–25 to estimate changes in these impacts associated with this final rulemaking.

As a substantial portion of CO₂ emitted into the atmosphere is not removed by natural processes for millennia, each unit of CO₂ not emitted into the atmosphere avoids some degree of effectively permanent climate change.

Therefore, reductions in emissions in the near term are important in determining climate impacts experienced not just over the next decades but over thousands of years.⁵⁶⁹ Though the magnitude of the avoided climate change projected here in isolation is small in comparison to the total projected changes, these reductions represent a reduction in the adverse risks associated with climate change (though these risks were not formally estimated for this action) across a range of equilibrium climate sensitivities. In addition, these reductions are part of a larger suite of domestic and international mitigation actions, and should be considered in that context.

EPA's analysis of this final rule's impact on global climate conditions is intended to quantify these potential reductions using the best available science. EPA's modeling results show consistent reductions relative to the baseline case in changes of CO₂ concentration, temperature, sea-level rise, and ocean pH over the next century.

⁵⁶⁹ National Research Council (NRC) (2011). Climate Stabilization Targets: Emissions, Concentrations, and Impacts over Decades to Millennia. National Academy Press. Washington, DC. (Docket EPA–HQ–OAR–2010–0799).

VIII. How will these rules impact non-GHG emissions and their associated effects?

The heavy-duty vehicle standards are expected to influence the emissions of criteria air pollutants and several hazardous air pollutants (air toxics). This section describes the projected impacts of the final rules on non-GHG emissions and air quality and the health and environmental effects associated with these pollutants. NHTSA further analyzes these projected health and environmental effects resulting from its final rules and reasonable alternatives in Chapter 4 of its FEIS.

A. Health Effects of Non-GHG Pollutants

In this section, we discuss health effects associated with exposure to some of the criteria and air toxic pollutants impacted by the final heavy-duty vehicle standards.

(1) Particulate Matter

(a) Background

Particulate matter is a highly complex mixture of solid particles and liquid droplets distributed among numerous atmospheric gases which interact with solid and liquid phases. Particles range in size from those smaller than 1 nanometer (10^{-9} meter) to over 100 micrometers (μm , or 10^{-6} meter) in diameter (for reference, a typical strand of human hair is 70 μm in diameter and a grain of salt is about 100 μm). Atmospheric particles can be grouped into several classes according to their aerodynamic and physical sizes. Generally, the three broad classes of particles include ultrafine particles (UFPs, generally considered as particulates with a diameter less than or equal to 0.1 μm [typically based on physical size, thermal diffusivity or electrical mobility]), “fine” particles ($\text{PM}_{2.5}$; particles with a nominal mean aerodynamic diameter less than or equal to 2.5 μm), and “thoracic” particles (PM_{10} ; particles with a nominal mean aerodynamic diameter less than or equal to 10 μm).⁵⁷⁰ Particles that fall within the size range between $\text{PM}_{2.5}$ and PM_{10} , are referred to as “thoracic coarse particles” ($\text{PM}_{10-2.5}$, particles with a nominal mean aerodynamic diameter less than or equal to 10 μm and greater than 2.5 μm). EPA currently has standards that regulate $\text{PM}_{2.5}$ and PM_{10} .⁵⁷¹

⁵⁷⁰ U.S. EPA. (2009). Integrated Science Assessment for Particulate Matter (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-08/139F. Figure 3–1.

⁵⁷¹ Regulatory definitions of PM size fractions, and information on reference and equivalent methods for measuring PM in ambient air, are

Particles span many sizes and shapes and may consist of hundreds of different chemicals. Particles are emitted directly from sources and are also formed through atmospheric chemical reactions; the former are often referred to as “primary” particles, and the latter as “secondary” particles. Particle concentration and composition varies by time of year and location, and, in addition to differences in source emissions, is affected by several weather-related factors, such as temperature, clouds, humidity, and wind. A further layer of complexity comes from particles’ ability to shift between solid/liquid and gaseous phases, which is influenced by concentration and meteorology, especially temperature.

Fine particles are produced primarily by combustion processes and by transformations of gaseous emissions (e.g., sulfur oxides (SO_x), oxides of nitrogen, and volatile organic compounds (VOC)) in the atmosphere. The chemical and physical properties of $\text{PM}_{2.5}$ may vary greatly with time, region, meteorology, and source category. Thus, $\text{PM}_{2.5}$ may include a complex mixture of different components including sulfates, nitrates, organic compounds, elemental carbon and metal compounds. These particles can remain in the atmosphere for days to weeks and travel hundreds to thousands of kilometers.

(b) Health Effects of PM

Scientific studies show exposure to ambient PM is associated with a broad range of health effects. These health effects are discussed in detail in the Integrated Science Assessment for Particulate Matter (PM ISA), which was finalized in December 2009.⁵⁷² The PM ISA summarizes health effects evidence for short- and long-term exposures to $\text{PM}_{2.5}$, $\text{PM}_{10-2.5}$, and ultrafine particles.⁵⁷³ The PM ISA concludes that human exposures to ambient $\text{PM}_{2.5}$ are associated with a number of adverse health effects and characterizes the weight of evidence for broad health categories (e.g., cardiovascular effects,

provided in 40 CFR parts 50, 53, and 58. With regard to national ambient air quality standards (NAAQS) which provide protection against health and welfare effects, the 24-hour PM_{10} standard provides protection against effects associated with short-term exposure to thoracic coarse particles (i.e., $\text{PM}_{10-2.5}$).

⁵⁷² U.S. EPA. (2009). Integrated Science Assessment for Particulate Matter (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-08/139F.

⁵⁷³ The ISA also evaluated evidence for PM components but did not reach causal determinations for components.

respiratory effects, etc.).⁵⁷⁴ The discussion below highlights the PM ISA’s conclusions pertaining to health effects associated with both short- and long-term PM exposures. Further discussion of health effects associated with PM can also be found in the rulemaking documents for the most recent review of the PM NAAQS completed in 2012.^{575 576}

EPA has concluded that “a causal relationship exists” between both long- and short-term exposures to $\text{PM}_{2.5}$ and premature mortality and cardiovascular effects and that “a causal relationship is likely to exist” between long- and short-term $\text{PM}_{2.5}$ exposures and respiratory effects. Further, there is evidence “suggestive of a causal relationship” between long-term $\text{PM}_{2.5}$ exposures and other health effects, including developmental and reproductive effects (e.g., low birth weight, infant mortality) and carcinogenic, mutagenic, and genotoxic effects (e.g., lung cancer mortality).⁵⁷⁷

As summarized in the final rule resulting from the last review (2012) of the PM NAAQS, and discussed extensively in the 2009 p.m. ISA, the available scientific evidence significantly strengthens the link between long- and short-term exposure to $\text{PM}_{2.5}$ and mortality, while providing indications that the magnitude of the $\text{PM}_{2.5}$ -mortality association with long-term exposures may be larger than previously estimated.^{578 579} The strongest evidence comes from recent

⁵⁷⁴ The causal framework draws upon the assessment and integration of evidence from across epidemiological, controlled human exposure, and toxicological studies, and the related uncertainties that ultimately influence our understanding of the evidence. This framework employs a five-level hierarchy that classifies the overall weight of evidence and causality using the following categorizations: causal relationship, likely to be causal relationship, suggestive of a causal relationship, inadequate to infer a causal relationship, and not likely to be a causal relationship (U.S. EPA. (2009). Integrated Science Assessment for Particulate Matter (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-08/139F, Table 1–3).

⁵⁷⁵ 78 FR 3103–3104, January 15, 2013.

⁵⁷⁶ 77 FR 38906–38911, June 29, 2012.

⁵⁷⁷ These causal inferences are based not only on the more expansive epidemiological evidence available in this review but also reflect consideration of important progress that has been made to advance our understanding of a number of potential biologic modes of action or pathways for PM-related cardiovascular and respiratory effects (U.S. EPA. (2009). Integrated Science Assessment for Particulate Matter (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-08/139F, Chapter 5).

⁵⁷⁸ 78 FR 3103–3104, January 15, 2013.

⁵⁷⁹ U.S. EPA. (2009). Integrated Science Assessment for Particulate Matter (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-08/139F, Chapter 6 (Section 6.5) and Chapter 7 (Section 7.6).

studies investigating long-term exposure to PM_{2.5} and cardiovascular-related mortality. The evidence supporting a causal relationship between long-term PM_{2.5} exposure and mortality also includes consideration of studies that demonstrated an improvement in community health following reductions in ambient fine particles.

Several studies evaluated in the 2009 p.m. ISA have examined the association between cardiovascular effects and long-term PM_{2.5} exposures in multi-city epidemiological studies conducted in the U.S. and Europe. These studies have provided new evidence linking long-term exposure to PM_{2.5} with an array of cardiovascular effects such as heart attacks, congestive heart failure, stroke, and mortality. This evidence is coherent with studies of effects associated with short-term exposure to PM_{2.5} that have observed associations with a continuum of effects ranging from subtle changes in indicators of cardiovascular health to serious clinical events, such as increased hospitalizations and emergency department visits due to cardiovascular disease and cardiovascular mortality.⁵⁸⁰

As detailed in the 2009 p.m. ISA, extended analyses of seminal epidemiological studies, as well as more recent epidemiological studies conducted in the U.S. and abroad, provide strong evidence of respiratory-related morbidity effects associated with long-term PM_{2.5} exposure. The strongest evidence for respiratory-related effects is from studies that evaluated decrements in lung function growth (in children), increased respiratory symptoms, and asthma development. The strongest evidence from short-term PM_{2.5} exposure studies has been observed for increased respiratory-related emergency department visits and hospital admissions for chronic obstructive pulmonary disease (COPD) and respiratory infections.⁵⁸¹

The body of scientific evidence detailed in the 2009 PM ISA is still limited with respect to associations between long-term PM_{2.5} exposures and developmental and reproductive effects as well as cancer, mutagenic, and genotoxic effects. The strongest evidence for an association between PM_{2.5} and developmental and

reproductive effects comes from epidemiological studies of low birth weight and infant mortality, especially due to respiratory causes during the post-neonatal period (*i.e.*, 1 month to 12 months of age).⁵⁸² With regard to cancer effects, “[m]ultiple epidemiologic studies have shown a consistent positive association between PM_{2.5} and lung cancer mortality, but studies have generally not reported associations between PM_{2.5} and lung cancer incidence.”⁵⁸³

In addition to evaluating the health effects attributed to short- and long-term exposure to PM_{2.5}, the 2009 PM ISA also evaluated whether specific components or sources of PM_{2.5} are more strongly associated with specific health effects. An evaluation of those studies resulted in the 2009 PM ISA concluding that “many [components] of PM can be linked with differing health effects and the evidence is not yet sufficient to allow differentiation of those [components] or sources that are more closely related to specific health outcomes.”⁵⁸⁴

For PM_{10-2.5}, the 2009 PM ISA concluded that available evidence was “suggestive of a causal relationship” between short-term exposures to PM_{10-2.5} and cardiovascular effects (*e.g.*, hospital admissions and Emergency Department (ED) visits, changes in cardiovascular function), respiratory effects (*e.g.*, ED visits and hospital admissions, increase in markers of pulmonary inflammation), and premature mortality. The scientific evidence was “inadequate to infer a causal relationship” between long-term exposure to PM_{10-2.5} and various health effects.^{585 586 587}

For UFPs, the 2009 PM ISA concluded that the evidence was “suggestive of a causal relationship” between short-term exposures and cardiovascular effects, including changes in heart rhythm and vasomotor function (the ability of blood vessels to

expand and contract). It also concluded that there was evidence “suggestive of a causal relationship” between short-term exposure to UFPs and respiratory effects, including lung function and pulmonary inflammation, with limited and inconsistent evidence for increases in ED visits and hospital admissions. Scientific evidence was “inadequate to infer a causal relationship” between short-term exposure to UFPs and additional health effects including premature mortality as well as long-term exposure to UFPs and all health outcomes evaluated.^{588 589}

The 2009 PM ISA conducted an evaluation of specific groups within the general population potentially at increased risk for experiencing adverse health effects related to PM exposures.^{590 591 592 593} The evidence detailed in the 2009 PM ISA expands our understanding of previously identified at-risk populations and lifestages (*i.e.*, children, older adults, and individuals with pre-existing heart and lung disease) and supports the identification of additional at-risk populations (*e.g.*, persons with lower socioeconomic status, genetic differences). Additionally, there is emerging, though still limited, evidence for additional potentially at-risk populations and lifestages, such as those with diabetes, people who are obese, pregnant women, and the developing fetus.⁵⁹⁴

(2) Ozone

(a) Background

Ground-level ozone pollution is typically formed through reactions involving VOC and NO_x in the lower atmosphere in the presence of sunlight. These pollutants, often referred to as ozone precursors, are emitted by many types of pollution sources, such as highway and nonroad motor vehicles and engines, power plants, chemical

plants, refineries, makers of consumer and commercial products, industrial facilities, and smaller area sources.

The science of ozone formation, transport, and accumulation is complex. Ground-level ozone is produced and destroyed in a cyclical set of chemical reactions, many of which are sensitive to temperature and sunlight. When ambient temperatures and sunlight levels remain high for several days and the air is relatively stagnant, ozone and its precursors can build up and result in more ozone than typically occurs on a single high-temperature day. Ozone and its precursors can be transported hundreds of miles downwind from precursor emissions, resulting in elevated ozone levels even in areas with low local VOC or NO_x emissions.

(b) Health Effects of Ozone

This section provides a summary of the health effects associated with exposure to ambient concentrations of ozone.⁵⁹⁵ The information in this section is based on the information and conclusions in the February 2013 Integrated Science Assessment for Ozone (Ozone ISA), which formed the basis for EPA's revision to the primary and secondary standards in 2015.⁵⁹⁶ The Ozone ISA concludes that human exposures to ambient concentrations of ozone are associated with a number of adverse health effects and characterizes the weight of evidence for these health effects.⁵⁹⁷ The discussion below highlights the Ozone ISA's conclusions pertaining to health effects associated with both short-term and long-term periods of exposure to ozone.

For short-term exposure to ozone, the Ozone ISA concludes that respiratory effects, including lung function decrements, pulmonary inflammation, exacerbation of asthma, respiratory-related hospital admissions, and

mortality, are causally associated with ozone exposure. It also concludes that cardiovascular effects, including decreased cardiac function and increased vascular disease, and total mortality are likely to be causally associated with short-term exposure to ozone and that evidence is suggestive of a causal relationship between central nervous system effects and short-term exposure to ozone.

For long-term exposure to ozone, the Ozone ISA concludes that respiratory effects, including new onset asthma, pulmonary inflammation and injury, are likely to be causally related with ozone exposure. The Ozone ISA characterizes the evidence as suggestive of a causal relationship for associations between long-term ozone exposure and cardiovascular effects, reproductive and developmental effects, central nervous system effects and total mortality. The evidence is inadequate to infer a causal relationship between chronic ozone exposure and increased risk of lung cancer.

Finally, inter-individual variation in human responses to ozone exposure can result in some groups being at increased risk for detrimental effects in response to exposure. In addition, some groups are at increased risk of exposure due to their activities, such as outdoor workers or children. The Ozone ISA identified several groups that are at increased risk for ozone-related health effects. These groups are people with asthma, children and older adults, individuals with reduced intake of certain nutrients (*i.e.*, Vitamins C and E), outdoor workers, and individuals having certain genetic variants related to oxidative metabolism or inflammation. Ozone exposure during childhood can have lasting effects through adulthood. Such effects include altered function of the respiratory and immune systems. Children absorb higher doses (normalized to lung surface area) of ambient ozone, compared to adults, due to their increased time spent outdoors, higher ventilation rates relative to body size, and a tendency to breathe a greater fraction of air through the mouth. Children also have a higher asthma prevalence compared to adults. Additional children's vulnerability and susceptibility factors are listed in Section XIV.

(3) Nitrogen Oxides

(a) Background

Oxides of nitrogen (NO_x) refers to nitric oxide and nitrogen dioxide (NO₂). For the NO_x NAAQS, NO₂ is the indicator. Most NO₂ is formed in the air through the oxidation of nitric oxide

(NO) emitted when fuel is burned at a high temperature. NO_x is also a major contributor to secondary PM_{2.5} formation. The health effects of ambient PM are discussed in Section VIII.A.1.b of this Preamble. NO_x and VOC are the two major precursors of ozone. The health effects of ozone are covered in Section VIII.A.2.b.

(b) Health Effects of Nitrogen Oxides

The most recent review of the health effects of oxides of nitrogen completed by EPA can be found in the 2016 Integrated Science Assessment for Oxides of Nitrogen—Health Criteria (Oxides of Nitrogen ISA).⁵⁹⁸ The primary source of NO₂ is motor vehicle emissions, and ambient NO₂ concentrations tend to be highly correlated with other traffic-related pollutants. Thus, a key issue in characterizing the causality of NO₂-health effect relationships was evaluating the extent to which studies supported an effect of NO₂ that is independent of other traffic-related pollutants. EPA concluded that the findings for asthma exacerbation integrated from epidemiologic and controlled human exposure studies provided evidence that is sufficient to infer a causal relationship between respiratory effects and short-term NO₂ exposure. The strongest evidence supporting an independent effect of NO₂ exposure comes from controlled human exposure studies demonstrating increased airway responsiveness in individuals with asthma following ambient-relevant NO₂ exposures. The coherence of this evidence with epidemiologic findings for asthma hospital admissions and ED visits as well as lung function decrements and increased pulmonary inflammation in children with asthma describe a plausible pathway by which NO₂ exposure can cause an asthma exacerbation. The 2016 ISA for Oxides of Nitrogen also concluded that there is likely to be a causal relationship between long-term NO₂ exposure and respiratory effects. This conclusion is based on new epidemiologic evidence for associations of NO₂ with asthma development in children combined with biological plausibility from experimental studies.

In evaluating a broader range of health effects, the 2016 ISA for Oxides of Nitrogen concluded evidence is “suggestive of, but not sufficient to infer, a causal relationship” between

⁵⁹⁵ Human exposure to ozone varies over time due to changes in ambient ozone concentration and because people move between locations which have notable different ozone concentrations. Also, the amount of ozone delivered to the lung is not only influenced by the ambient concentrations but also by the individuals breathing route and rate.

⁵⁹⁶ U.S. EPA. Integrated Science Assessment of Ozone and Related Photochemical Oxidants (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-10/076F, 2013. The ISA is available at <http://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=247492#Download>.

⁵⁹⁷ The ISA evaluates evidence and draws conclusions on the causal nature of relationship between relevant pollutant exposures and health effects, assigning one of five “weight of evidence” determinations: causal relationship, likely to be a causal relationship, suggestive of, but not sufficient to infer, a causal relationship, inadequate to infer a causal relationship, and not likely to be a causal relationship. For more information on these levels of evidence, please refer to Table II in the Preamble of the ISA.

⁵⁹⁸ U.S. EPA. Integrated Science Assessment for Oxides of Nitrogen—Health Criteria (2016 Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-15/068, 2016.

short-term NO₂ exposure and cardiovascular effects and mortality and between long-term NO₂ exposure and cardiovascular effects and diabetes, birth outcomes, and cancer. In addition, the scientific evidence is inadequate (insufficient consistency of epidemiologic and toxicological evidence) to infer a causal relationship for long-term NO₂ exposure with fertility, reproduction, and pregnancy, as well as with postnatal development. A key uncertainty in understanding the relationship between these non-respiratory health effects and short- or long-term exposure to NO₂ is copollutant confounding, particularly by other roadway pollutants. The available evidence for non-respiratory health effects does not adequately address whether NO₂ has an independent effect or whether it primarily represents effects related to other or a mixture of traffic-related pollutants.

The 2016 ISA for Oxides of Nitrogen concluded that people with asthma, children, and older adults are at increased risk for NO₂-related health effects. In these groups and lifestages, NO₂ is consistently related to larger effects on outcomes related to asthma exacerbation, for which there is confidence in the relationship with NO₂ exposure.

(4) Sulfur Oxides

(a) Background

Sulfur dioxide (SO₂), a member of the sulfur oxide (SO_x) family of gases, is formed from burning fuels containing sulfur (e.g., coal or oil derived), extracting gasoline from oil, or extracting metals from ore. SO₂ and its gas phase oxidation products can dissolve in water droplets and further oxidize to form sulfuric acid which reacts with ammonia to form sulfates, which are important components of ambient PM. The health effects of ambient PM are discussed in Section VIII.A.1.b of this Preamble.

(b) Health Effects of SO₂

Information on the health effects of SO₂ can be found in the 2008 Integrated Science Assessment for Sulfur Oxides—Health Criteria (SO_x ISA).⁵⁹⁹ Short-term peaks (5–10 minutes) of SO₂ have long been known to cause adverse respiratory health effects, particularly among individuals with asthma. In addition to those with asthma (both children and

adults), potentially at-risk lifestages include all children and the elderly. During periods of elevated ventilation, asthmatics may experience symptomatic bronchoconstriction within minutes of exposure. Following an extensive evaluation of health evidence from epidemiologic and laboratory studies, EPA concluded that there is a causal relationship between respiratory health effects and short-term exposure to SO₂. Separately, based on an evaluation of the epidemiologic evidence of associations between short-term exposure to SO₂ and mortality, EPA concluded that the overall evidence is suggestive of a causal relationship between short-term exposure to SO₂ and mortality. Additional information on the health effects of SO₂ is available in Chapter 6.1.1.4.2 of the RIA.

(5) Carbon Monoxide

(a) Background

Carbon monoxide (CO) is a colorless, odorless gas emitted from combustion processes. Nationally, particularly in urban areas, the majority of CO emissions to ambient air come from mobile sources.⁶⁰⁰

(b) Health Effects of Carbon Monoxide

Information on the health effects of CO can be found in the January 2010 Integrated Science Assessment for Carbon Monoxide (CO ISA).⁶⁰¹ The CO ISA presents conclusions regarding the presence of causal relationships between CO exposure and categories of adverse health effects.⁶⁰² This section provides a summary of the health effects associated with exposure to ambient concentrations of CO, along with the ISA conclusions.⁶⁰³

Controlled human exposure studies of subjects with coronary artery disease

⁵⁹⁹ U.S. EPA, (2010). Integrated Science Assessment for Carbon Monoxide (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-09/019F, 2010. Available at <http://cfpub.epa.gov/ncea/cfm/recorddisplay.cfm?deid=218686>. See Section 2.1.

⁶⁰¹ U.S. EPA, (2010). Integrated Science Assessment for Carbon Monoxide (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-09/019F, 2010. Available at <http://cfpub.epa.gov/ncea/cfm/recorddisplay.cfm?deid=218686>.

⁶⁰² The ISA evaluates the health evidence associated with different health effects, assigning one of five “weight of evidence” determinations: causal relationship, likely to be a causal relationship, suggestive of a causal relationship, inadequate to infer a causal relationship, and not likely to be a causal relationship. For definitions of these levels of evidence, please refer to Section 1.6 of the ISA.

⁶⁰³ Personal exposure includes contributions from many sources, and in many different environments. Total personal exposure to CO includes both ambient and nonambient components; and both components may contribute to adverse health effects.

show a decrease in the time to onset of exercise-induced angina (chest pain) and electrocardiogram changes following CO exposure. In addition, epidemiologic studies observed associations between short-term CO exposure and cardiovascular morbidity, particularly increased emergency room visits and hospital admissions for coronary heart disease (including ischemic heart disease, myocardial infarction, and angina). Some epidemiologic evidence is also available for increased hospital admissions and emergency room visits for congestive heart failure and cardiovascular disease as a whole. The CO ISA concludes that a causal relationship is likely to exist between short-term exposures to CO and cardiovascular morbidity. It also concludes that available data are inadequate to conclude that a causal relationship exists between long-term exposures to CO and cardiovascular morbidity.

Animal studies show various neurological effects with in-utero CO exposure. Controlled human exposure studies report central nervous system and behavioral effects following low-level CO exposures, although the findings have not been consistent across all studies. The CO ISA concludes the evidence is suggestive of a causal relationship with both short- and long-term exposure to CO and central nervous system effects.

A number of studies cited in the CO ISA have evaluated the role of CO exposure in birth outcomes such as preterm birth or cardiac birth defects. There is limited epidemiologic evidence of a CO-induced effect on preterm births and birth defects, with weak evidence for a decrease in birth weight. Animal toxicological studies have found perinatal CO exposure to affect birth weight, as well as other developmental outcomes. The CO ISA concludes the evidence is suggestive of a causal relationship between long-term exposures to CO and developmental effects and birth outcomes.

Epidemiologic studies provide evidence of associations between short-term CO concentrations and respiratory morbidity such as changes in pulmonary function, respiratory symptoms, and hospital admissions. A limited number of epidemiologic studies considered copollutants such as ozone, SO₂, and PM in two-pollutant models and found that CO risk estimates were generally robust, although this limited evidence makes it difficult to disentangle effects attributed to CO itself from those of the larger complex air pollution mixture. Controlled human exposure studies have not extensively

⁵⁹⁹ U.S. EPA. (2008). *Integrated Science Assessment (ISA) for Sulfur Oxides—Health Criteria (Final Report)*. EPA/600/R-08/047F. Washington, DC: U.S. Environmental Protection Agency.

evaluated the effect of CO on respiratory morbidity. Animal studies at levels of 50–100 ppm CO show preliminary evidence of altered pulmonary vascular remodeling and oxidative injury. The CO ISA concludes that the evidence is suggestive of a causal relationship between short-term CO exposure and respiratory morbidity, and inadequate to conclude that a causal relationship exists between long-term exposure and respiratory morbidity.

Finally, the CO ISA concludes that the epidemiologic evidence is suggestive of a causal relationship between short-term concentrations of CO and mortality. Epidemiologic evidence suggests an association exists between short-term exposure to CO and mortality, but limited evidence is available to evaluate cause-specific mortality outcomes associated with CO exposure. In addition, the attenuation of CO risk estimates which was often observed in copollutant models contributes to the uncertainty as to whether CO is acting alone or as an indicator for other combustion-related pollutants. The CO ISA also concludes that there is not likely to be a causal relationship between relevant long-term exposures to CO and mortality.

(6) Diesel Exhaust

(a) Background

Diesel exhaust consists of a complex mixture composed of particulate matter, carbon dioxide, oxygen, nitrogen, water vapor, carbon monoxide, nitrogen compounds, sulfur compounds and numerous low-molecular-weight hydrocarbons. A number of these gaseous hydrocarbon components are individually known to be toxic, including aldehydes, benzene and 1,3-butadiene. The diesel particulate matter present in diesel exhaust consists mostly of fine particles (<2.5 μm), of which a significant fraction is ultrafine particles (<0.1 μm). These particles have a large surface area which makes them an excellent medium for adsorbing organics, and their small size makes them highly respirable. Many of the organic compounds present in the gases and on the particles, such as polycyclic organic matter, are individually known to have mutagenic and carcinogenic properties.

Diesel exhaust varies significantly in chemical composition and particle sizes between different engine types (heavy-duty, light-duty), engine operating conditions (idle, acceleration, deceleration), and fuel formulations (high/low sulfur fuel). Also, there are emissions differences between on-road and nonroad engines because the

nonroad engines are generally of older technology. After being emitted in the engine exhaust, diesel exhaust undergoes dilution as well as chemical and physical changes in the atmosphere. The lifetime for some of the compounds present in diesel exhaust ranges from hours to days.

(b) Health Effects of Diesel Exhaust

In EPA's 2002 Diesel Health Assessment Document (Diesel HAD), exposure to diesel exhaust was classified as likely to be carcinogenic to humans by inhalation from environmental exposures, in accordance with the revised draft 1996/1999 EPA cancer guidelines.⁶⁰⁴ A number of other agencies (National Institute for Occupational Safety and Health, the International Agency for Research on Cancer, the World Health Organization, California EPA, and the U.S. Department of Health and Human Services) had made similar hazard classifications prior to 2002. EPA also concluded in the 2002 Diesel HAD that it was not possible to calculate a cancer unit risk for diesel exhaust due to limitations in the exposure data for the occupational groups or the absence of a dose-response relationship.

In the absence of a cancer unit risk, the Diesel HAD sought to provide additional insight into the significance of the diesel exhaust cancer hazard by estimating possible ranges of risk that might be present in the population. An exploratory analysis was used to characterize a range of possible lung cancer risk. The outcome was that environmental risks of cancer from long-term diesel exhaust exposures could plausibly range from as low as 10^{-5} to as high as 10^{-3} . Because of uncertainties, the analysis acknowledged that the risks could be lower than 10^{-5} , and a zero risk from diesel exhaust exposure could not be ruled out.

Non-cancer health effects of acute and chronic exposure to diesel exhaust emissions are also of concern to EPA. EPA derived a diesel exhaust reference concentration (RfC) from consideration of four well-conducted chronic rat inhalation studies showing adverse pulmonary effects. The RfC is 5 $\mu\text{g}/\text{m}^3$ for diesel exhaust measured as diesel

particulate matter. This RfC does not consider allergenic effects such as those associated with asthma or immunologic or the potential for cardiac effects. There was emerging evidence in 2002, discussed in the Diesel HAD, that exposure to diesel exhaust can exacerbate these effects, but the exposure-response data were lacking at that time to derive an RfC based on these then-emerging considerations. The EPA Diesel HAD states, "With [diesel particulate matter] being a ubiquitous component of ambient PM, there is an uncertainty about the adequacy of the existing [diesel exhaust] noncancer database to identify all of the pertinent [diesel exhaust]-caused noncancer health hazards." The Diesel HAD also notes "that acute exposure to [diesel exhaust] has been associated with irritation of the eye, nose, and throat, respiratory symptoms (cough and phlegm), and neurophysiological symptoms such as headache, lightheadedness, nausea, vomiting, and numbness or tingling of the extremities." The Diesel HAD noted that the cancer and noncancer hazard conclusions applied to the general use of diesel engines then on the market and as cleaner engines replace a substantial number of existing ones, the applicability of the conclusions would need to be reevaluated.

It is important to note that the Diesel HAD also briefly summarizes health effects associated with ambient PM and discusses EPA's then-annual $\text{PM}_{2.5}$ NAAQS of 15 $\mu\text{g}/\text{m}^3$. In 2012, EPA revised the annual $\text{PM}_{2.5}$ NAAQS to 12 $\mu\text{g}/\text{m}^3$. There is a large and extensive body of human data showing a wide spectrum of adverse health effects associated with exposure to ambient PM, of which diesel exhaust is an important component. The $\text{PM}_{2.5}$ NAAQS is designed to provide protection from the noncancer health effects and premature mortality attributed to exposure to $\text{PM}_{2.5}$. The contribution of diesel PM to total ambient PM varies in different regions of the country and also, within a region, from one area to another. The contribution can be high in near-roadway environments, for example, or in other locations where diesel engine use is concentrated.

Since 2002, several new studies have been published which continue to report increased lung cancer risk with occupational exposure to diesel exhaust from older engines. Of particular note since 2011 are three new epidemiology studies which have examined lung cancer in occupational populations, for example, truck drivers, underground nonmetal miners and other diesel

⁶⁰⁴ U.S. EPA. (1999). *Guidelines for Carcinogen Risk Assessment*. Review Draft. NCEA-F-0644, July. Washington, DC: U.S. EPA. Retrieved on March 19, 2009 from <http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=54932>.

⁶⁰⁵ U.S. EPA (2002). *Health Assessment Document for Diesel Engine Exhaust*. EPA/600/8-90/057F Office of Research and Development, Washington DC. Retrieved on March 17, 2009 from <http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=29060>. pp. 1-1 1-2.

motor-related occupations. These studies reported increased risk of lung cancer with exposure to diesel exhaust with evidence of positive exposure-response relationships to varying degrees.^{606 607 608} These newer studies (along with others that have appeared in the scientific literature) add to the evidence EPA evaluated in the 2002 Diesel HAD and further reinforces the concern that diesel exhaust exposure likely poses a lung cancer hazard. The findings from these newer studies do not necessarily apply to newer technology diesel engines since the newer engines have large reductions in the emission constituents compared to older technology diesel engines.

In light of the growing body of scientific literature evaluating the health effects of exposure to diesel exhaust, in June 2012 the World Health Organization's International Agency for Research on Cancer (IARC), a recognized international authority on the carcinogenic potential of chemicals and other agents, evaluated the full range of cancer-related health effects data for diesel engine exhaust. IARC concluded that diesel exhaust should be regarded as "carcinogenic to humans."⁶⁰⁹ This designation was an update from its 1988 evaluation that considered the evidence to be indicative of a "probable human carcinogen."

(7) Air Toxics

(a) Background

Heavy-duty vehicle emissions contribute to ambient levels of air toxics that are known or suspected human or animal carcinogens, or that have noncancer health effects. The population experiences an elevated risk of cancer and other noncancer health effects from exposure to the class of pollutants known collectively as "air toxics."⁶¹⁰ These compounds include,

but are not limited to, benzene, 1,3-butadiene, formaldehyde, acetaldehyde, acrolein, polycyclic organic matter, and naphthalene. These compounds were identified as national or regional risk drivers or contributors in the 2011 National-scale Air Toxics Assessment and have significant inventory contributions from mobile sources.⁶¹¹

(b) Benzene

EPA's Integrated Risk Information System (IRIS) database lists benzene as a known human carcinogen (causing leukemia) by all routes of exposure, and concludes that exposure is associated with additional health effects, including genetic changes in both humans and animals and increased proliferation of bone marrow cells in mice.^{612 613 614} EPA states in its IRIS database that data indicate a causal relationship between benzene exposure and acute lymphocytic leukemia and suggest a relationship between benzene exposure and chronic non-lymphocytic leukemia and chronic lymphocytic leukemia. EPA's IRIS documentation for benzene also lists a range of 2.2×10^{-6} to 7.8×10^{-6} per $\mu\text{g}/\text{m}^3$ as the unit risk estimate (URE) for benzene.^{615 616} The International Agency for Research on Cancer (IARC) has determined that benzene is a human carcinogen and the U.S. Department of Health and Human Services (DHHS) has characterized benzene as a known human carcinogen.^{617 618}

A number of adverse noncancer health effects including blood disorders, such as pre-leukemia and aplastic anemia, have also been associated with long-term exposure to benzene.^{619 620} The most sensitive noncancer effect observed in humans, based on current data, is the depression of the absolute lymphocyte count in blood.^{621 622} EPA's inhalation reference concentration (RfC) for benzene is 30 $\mu\text{g}/\text{m}^3$. The RfC is based on suppressed absolute lymphocyte counts seen in humans under occupational exposure conditions. In addition, recent work, including studies sponsored by the Health Effects Institute, provides evidence that biochemical responses are occurring at lower levels of benzene exposure than previously known.^{623 624 625 626} EPA's IRIS program has not yet evaluated these new data. EPA does not currently have an acute reference concentration for benzene. The Agency for Toxic Substances and Disease Registry (ATSDR) Minimal Risk Level (MRL) for acute exposure to benzene is 29 $\mu\text{g}/\text{m}^3$ for 1–14 days exposure.^{627 628}

(c) 1,3-Butadiene

EPA has characterized 1,3-butadiene as carcinogenic to humans by inhalation.^{629 630} The IARC has determined that 1,3-butadiene is a human carcinogen and the U.S. DHHS has characterized 1,3-butadiene as a known human carcinogen.^{631 632 633} There are numerous studies consistently demonstrating that 1,3-butadiene is metabolized into genotoxic metabolites by experimental animals and humans. The specific mechanisms of 1,3-butadiene-induced carcinogenesis are unknown; however, the scientific evidence strongly suggests that the carcinogenic effects are mediated by genotoxic metabolites. Animal data suggest that females may be more sensitive than males for cancer effects associated with 1,3-butadiene exposure; there are insufficient data in humans from which to draw conclusions about sensitive subpopulations. The URE for 1,3-butadiene is 3×10^{-5} per $\mu\text{g}/\text{m}^3$.⁶³⁴ 1,3-butadiene also causes a variety of reproductive and developmental effects in mice; no human data on these effects are available. The most sensitive effect was ovarian atrophy observed in a lifetime bioassay of female mice.⁶³⁵

hazardous substance that is likely to be without appreciable risk of adverse noncancer health effects over a specified duration of exposure.

Based on this critical effect and the benchmark concentration methodology, an RfC for chronic health effects was calculated at 0.9 ppb (approximately 2 $\mu\text{g}/\text{m}^3$).

(d) Formaldehyde

In 1991, EPA concluded that formaldehyde is a carcinogen based on nasal tumors in animal bioassays.⁶³⁶ An Inhalation URE for cancer and a Reference Dose for oral noncancer effects were developed by the agency and posted on the IRIS database. Since that time, the National Toxicology Program (NTP) and International Agency for Research on Cancer (IARC) have concluded that formaldehyde is a known human carcinogen.^{637 638}

The conclusions by IARC and NTP reflect the results of epidemiologic research published since 1991 in combination with previous animal, human and mechanistic evidence. Research conducted by the National Cancer Institute reported an increased risk of nasopharyngeal cancer and specific lymph hematopoietic malignancies among workers exposed to formaldehyde.^{639 640 641} A National Institute of Occupational Safety and Health study of garment workers also reported increased risk of death due to leukemia among workers exposed to formaldehyde.⁶⁴² Extended follow-up of a cohort of British chemical workers did not report evidence of an increase in nasopharyngeal or lymph hematopoietic cancers, but a continuing statistically significant excess in lung cancers was reported.⁶⁴³ Finally, a study of

⁶⁴³ Coggon, D., EC Harris, J Poole, KT Palmer. 2003. Extended follow-up of a cohort of British

embalmers reported formaldehyde exposures to be associated with an increased risk of myeloid leukemia but not brain cancer.⁶⁴⁴

Health effects of formaldehyde in addition to cancer were reviewed by the Agency for Toxic Substances and Disease Registry in 1999⁶⁴⁵, supplemented in 2010,⁶⁴⁶ and by the World Health Organization.⁶⁴⁷ These organizations reviewed the scientific literature concerning health effects linked to formaldehyde exposure to evaluate hazards and dose response relationships and defined exposure concentrations for minimal risk levels (MRLs). The health endpoints reviewed included sensory irritation of eyes and respiratory tract, reduced pulmonary function, nasal histopathology, and immune system effects. In addition, research on reproductive and developmental effects and neurological effects were discussed along with several studies that suggest that formaldehyde may increase the risk of asthma—particularly in the young.

EPA released a draft Toxicological Review of Formaldehyde—Inhalation Assessment through the IRIS program for peer review by the National Research Council (NRC) and public comment in June 2010.⁶⁴⁸ The draft assessment reviewed more recent research from animal and human studies on cancer and other health effects. The NRC released their review report in April 2011.⁶⁴⁹ EPA is currently developing a revised draft assessment in response to this review.

(e) Acetaldehyde

Acetaldehyde is classified in EPA's IRIS database as a probable human carcinogen, based on nasal tumors in rats, and is considered toxic by the inhalation, oral, and intravenous routes.⁶⁵⁰ The URE in IRIS for acetaldehyde is 2.2×10^{-6} per $\mu\text{g}/\text{m}^3$.⁶⁵¹ Acetaldehyde is reasonably anticipated to be a human carcinogen by the U.S. DHHS in the 13th Report on Carcinogens and is classified as possibly carcinogenic to humans (Group 2B) by the IARC.^{652 653} Acetaldehyde is currently listed on the IRIS Program Multi-Year Agenda for reassessment within the next few years.

The primary noncancer effects of exposure to acetaldehyde vapors include irritation of the eyes, skin, and respiratory tract.⁶⁵⁴ In short-term (4 week) rat studies, degeneration of olfactory epithelium was observed at various concentration levels of acetaldehyde exposure.^{655 656} Data from these studies were used by EPA to develop an inhalation reference concentration of $9 \mu\text{g}/\text{m}^3$. Some asthmatics have been shown to be a sensitive subpopulation to decrements in functional expiratory volume (FEV1 test) and bronchoconstriction upon acetaldehyde inhalation.⁶⁵⁷

(f) Acrolein

EPA most recently evaluated the toxicological and health effects

literature related to acrolein in 2003 and concluded that the human carcinogenic potential of acrolein could not be determined because the available data were inadequate. No information was available on the carcinogenic effects of acrolein in humans and the animal data provided inadequate evidence of carcinogenicity.⁶⁵⁸ The IARC determined in 1995 that acrolein was not classifiable as to its carcinogenicity in humans.⁶⁵⁹

Lesions to the lungs and upper respiratory tract of rats, rabbits, and hamsters have been observed after subchronic exposure to acrolein.⁶⁶⁰ The agency has developed an RfC for acrolein of $0.02 \mu\text{g}/\text{m}^3$ and an RfD of $0.5 \mu\text{g}/\text{kg}\cdot\text{day}$.⁶⁶¹

Acrolein is extremely acrid and irritating to humans when inhaled, with acute exposure resulting in upper respiratory tract irritation, mucus hypersecretion and congestion. The intense irritancy of this carbonyl has been demonstrated during controlled tests in human subjects, who suffer intolerable eye and nasal mucosal sensory reactions within minutes of exposure.⁶⁶² These data and additional studies regarding acute effects of human exposure to acrolein are summarized in EPA's 2003 Toxicological Review of Acrolein.⁶⁶³ Studies in humans indicate that levels as low as 0.09 ppm ($0.21 \text{ mg}/\text{m}^3$) for five minutes may elicit subjective complaints of eye irritation

with increasing concentrations leading to more extensive eye, nose and respiratory symptoms. Acute exposures in animal studies report bronchial hyper-responsiveness. Based on animal data (more pronounced respiratory irritancy in mice with allergic airway disease in comparison to non-diseased mice)⁶⁶⁴ and demonstration of similar effects in humans (*e.g.*, reduction in respiratory rate), individuals with compromised respiratory function (*e.g.*, emphysema, asthma) are expected to be at increased risk of developing adverse responses to strong respiratory irritants such as acrolein. EPA does not currently have an acute reference concentration for acrolein. The available health effect reference values for acrolein have been summarized by EPA and include an ATSDR MRL for acute exposure to acrolein of $7 \mu\text{g}/\text{m}^3$ for 1–14 days exposure; and Reference Exposure Level (REL) values from the California Office of Environmental Health Hazard Assessment (OEHHA) for one-hour and 8-hour exposures of $2.5 \mu\text{g}/\text{m}^3$ and $0.7 \mu\text{g}/\text{m}^3$, respectively.⁶⁶⁵

(g) Polycyclic Organic Matter

The term polycyclic organic matter (POM) defines a broad class of compounds that includes the polycyclic aromatic hydrocarbon compounds (PAHs). One of these compounds, naphthalene, is discussed separately below. POM compounds are formed primarily from combustion and are present in the atmosphere in gas and particulate form. Cancer is the major concern from exposure to POM. Epidemiologic studies have reported an increase in lung cancer in humans exposed to diesel exhaust, coke oven emissions, roofing tar emissions, and cigarette smoke; all of these mixtures contain POM compounds.^{666 667} Animal studies have reported respiratory tract tumors from inhalation exposure to

benzo[a]pyrene and alimentary tract and liver tumors from oral exposure to benzo[a]pyrene.⁶⁶⁸ In 1997 EPA classified seven PAHs (benzo[a]pyrene, benz[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, dibenz[a,h]anthracene, and indeno[1,2,3-cd]pyrene) as Group B2, probable human carcinogens.⁶⁶⁹ Since that time, studies have found that maternal exposures to PAHs in a population of pregnant women were associated with several adverse birth outcomes, including low birth weight and reduced length at birth, as well as impaired cognitive development in preschool children (3 years of age).^{670 671} These and similar studies are being evaluated as a part of the ongoing IRIS reassessment of health effects associated with exposure to benzo[a]pyrene.

(h) Naphthalene

Naphthalene is found in small quantities in gasoline and diesel fuels. Naphthalene emissions have been measured in larger quantities in both gasoline and diesel exhaust compared with evaporative emissions from mobile sources, indicating it is primarily a product of combustion. Acute (short-term) exposure of humans to naphthalene by inhalation, ingestion, or dermal contact is associated with hemolytic anemia and damage to the liver and the nervous system.⁶⁷² Chronic (long term) exposure of workers and rodents to naphthalene has been reported to cause cataracts and retinal damage.⁶⁷³ EPA released an external

review draft of a reassessment of the inhalation carcinogenicity of naphthalene based on a number of recent animal carcinogenicity studies.⁶⁷⁴ The draft reassessment completed external peer review.⁶⁷⁵ Based on external peer review comments received, a revised draft assessment that considers all routes of exposure, as well as cancer and noncancer effects, is under development. The external review draft does not represent official agency opinion and was released solely for the purposes of external peer review and public comment. The National Toxicology Program listed naphthalene as “reasonably anticipated to be a human carcinogen” in 2004 on the basis of bioassays reporting clear evidence of carcinogenicity in rats and some evidence of carcinogenicity in mice.⁶⁷⁶ California EPA has released a new risk assessment for naphthalene, and the IARC has reevaluated naphthalene and re-classified it as Group 2B: possibly carcinogenic to humans.⁶⁷⁷

Naphthalene also causes a number of chronic non-cancer effects in animals, including abnormal cell changes and growth in respiratory and nasal tissues.⁶⁷⁸ The current EPA IRIS assessment includes noncancer data on hyperplasia and metaplasia in nasal tissue that form the basis of the inhalation RfC of 3 µg/m³.⁶⁷⁹ The

ATSDR MRL for acute exposure to naphthalene is 0.6 mg/kg/day.

(i) Other Air Toxics

In addition to the compounds described above, other compounds in gaseous hydrocarbon and PM emissions from motor vehicles will be affected by this action. Mobile source air toxic compounds that will potentially be impacted include ethylbenzene, propionaldehyde, toluene, and xylene. Information regarding the health effects of these compounds can be found in EPA's IRIS database.⁶⁸⁰

(8) Exposure and Health Effects Associated With Traffic

Locations in close proximity to major roadways generally have elevated concentrations of many air pollutants emitted from motor vehicles. Hundreds of such studies have been published in peer-reviewed journals, concluding that concentrations of CO, NO, NO₂, benzene, aldehydes, particulate matter, black carbon, and many other compounds are elevated in ambient air within approximately 300–600 meters (about 1,000–2,000 feet) of major roadways. Highest concentrations of most pollutants emitted directly by motor vehicles are found at locations within 50 meters (about 165 feet) of the edge of a roadway's traffic lanes.

A large-scale review of air quality measurements in the vicinity of major roadways between 1978 and 2008 concluded that the pollutants with the steepest concentration gradients in vicinities of roadways were CO, ultrafine particles, metals, elemental carbon (EC), NO, NO_x, and several VOCs.⁶⁸¹ These pollutants showed a large reduction in concentrations within 100 meters downwind of the roadway. Pollutants that showed more gradual reductions with distance from roadways included benzene, NO₂, PM_{2.5}, and PM₁₀. In the review article, results varied based on the method of statistical analysis used to determine the trend.

For pollutants with relatively high background concentrations relative to near-road concentrations, detecting concentration gradients can be difficult. For example, many aldehydes have high background concentrations as a result of photochemical breakdown of precursors from many different organic compounds. This can make detection of gradients around roadways and other primary emission sources difficult.

However, several studies have measured aldehydes in multiple weather conditions and found higher concentrations of many carbonyls downwind of roadways.^{682 683} These findings suggest a substantial roadway source of these carbonyls.

In the past 15 years, many studies have been published with results reporting that populations who live, work, or go to school near high-traffic roadways experience higher rates of numerous adverse health effects, compared to populations far away from major roads.⁶⁸⁴ In addition, numerous studies have found adverse health effects associated with spending time in traffic, such as commuting or walking along high-traffic roadways.^{685 686 687 688} The health outcomes with the strongest evidence linking them with traffic-associated air pollutants are respiratory effects, particularly in asthmatic children, and cardiovascular effects.

Numerous reviews of this body of health literature have been published as well. In 2010, an expert panel of the Health Effects Institute (HEI) published a review of hundreds of exposure, epidemiology, and toxicology studies.⁶⁸⁹ The panel rated how the evidence for each type of health outcome supported a conclusion of a causal association with traffic-

associated air pollution as either "sufficient," "suggestive but not sufficient," or "inadequate and insufficient." The panel categorized evidence of a causal association for exacerbation of childhood asthma as "sufficient." The panel categorized evidence of a causal association for new onset asthma as between "sufficient" and "suggestive but not sufficient." "Suggestive of a causal association" was how the panel categorized evidence linking traffic-associated air pollutants with exacerbation of adult respiratory symptoms and lung function decrement. It categorized as "inadequate and insufficient" evidence of a causal relationship between traffic-related air pollution and health care utilization for respiratory problems, new onset adult asthma, chronic obstructive pulmonary disease (COPD), nonasthmatic respiratory allergy, and cancer in adults and children. Other literature reviews have been published with conclusions generally similar to the HEI panel's.^{690 691 692 693} However, in 2014, researchers from the U.S. Centers for Disease Control and Prevention (CDC) published a systematic review and meta-analysis of studies evaluating the risk of childhood leukemia associated with traffic exposure and reported positive associations between "postnatal" proximity to traffic and leukemia risks, but no such association for "prenatal" exposures.⁶⁹⁴

Health outcomes with few publications suggest the possibility of other effects still lacking sufficient evidence to draw definitive conclusions. Among these outcomes with a small number of positive studies are neurological impacts (e.g., autism and reduced cognitive function) and reproductive outcomes (e.g., preterm birth, low birth weight).^{695 696 697 698}

In addition to health outcomes, particularly cardiopulmonary effects, conclusions of numerous studies suggest mechanisms by which traffic-related air pollution affects health. Numerous studies indicate that near-roadway exposures may increase systemic inflammation, affecting organ systems, including blood vessels and lungs.^{699 700 701 702} Long-term exposures in near-road environments have been associated with inflammation-associated conditions, such as atherosclerosis and asthma.^{703 704 705}

Several studies suggest that some factors may increase susceptibility to the effects of traffic-associated air pollution. Several studies have found stronger respiratory associations in children experiencing chronic social stress, such as in violent neighborhoods or in homes with high family stress.^{706 707 708}

Continued

The risks associated with residence, workplace, or schools near major roads are of potentially high public health significance due to the large population in such locations. According to the 2009 American Housing Survey, over 22 million homes (17.0 percent of all U.S. housing units) were located within 300 feet of an airport, railroad, or highway with four or more lanes. This corresponds to a population of more than 50 million U.S. residents in close proximity to high-traffic roadways or other transportation sources. Based on 2010 Census data, a 2013 publication estimated that 19 percent of the U.S. population (over 59 million people) lived within 500 meters of roads with at least 25,000 annual average daily traffic (AADT), while about 3.2 percent of the population lived within 100 meters (about 300 feet) of such roads.⁷⁰⁹ Another 2013 study estimated that 3.7 percent of the U.S. population (about 11.3 million people) lived within 150 meters (about 500 feet) of interstate highways or other freeways and expressways.⁷¹⁰ As discussed in Section VIII.A.(9), on average, populations near major roads have higher fractions of minority residents and lower socioeconomic status. Furthermore, on average, Americans spend more than an hour traveling each day, bringing nearly all residents into a high-exposure microenvironment for part of the day.

In light of these concerns, EPA has required through the NAAQS process that air quality monitors be placed near high-traffic roadways for determining concentrations of CO, NO₂, and PM_{2.5} (in addition to those existing monitors located in neighborhoods and other locations farther away from pollution sources). Near-roadway monitors for NO₂ begin operation between 2014 and 2017 in Core Based Statistical Areas (CBSAs) with population of at least 500,000. Monitors for CO and PM_{2.5} begin operation between 2015 and 2017. These monitors will further our

understanding of exposure in these locations.

EPA and DOT continue to research near-road air quality, including the types of pollutants found in high concentrations near major roads and health problems associated with the mixture of pollutants near roads.

(9) Environmental Justice

Environmental justice (EJ) is a principle asserting that all people deserve fair treatment and meaningful involvement with respect to environmental laws, regulations, and policies. EPA seeks to provide the same degree of protection from environmental health hazards for all people. DOT shares this goal and is informed about the potential environmental impacts of its rulemakings through its NEPA process (see NHTSA's DEIS). As referenced below, numerous studies have found that some environmental hazards are more prevalent in areas where racial/ethnic minorities and people with low socioeconomic status (SES) represent a higher fraction of the population compared with the general population. In addition, compared to non-Hispanic whites, some types of minorities may have greater levels of health problems during some life stages. For example, in 2014, about 13 percent of Black, non-Hispanic and 24 percent of Puerto Rican children were estimated to currently have asthma, compared with 8 percent of white, non-Hispanic children.⁷¹¹

As discussed in Section VIII.A.(8) of this document and NHTSA's FEIS, concentrations of many air pollutants are elevated near high-traffic roadways. If minority populations and low-income populations disproportionately live near such roads, then an issue of EJ may be present. We reviewed existing scholarly literature examining the potential for disproportionate exposure among minorities and people with low SES, and we conducted our own evaluation of two national datasets: The U.S. Census Bureau's American Housing Survey for calendar year 2009 and the U.S. Department of Education's database of school locations.

Publications that address EJ issues generally report that populations living near major roadways (and other types of transportation infrastructure) tend to be composed of larger fractions of nonwhite residents. People living in neighborhoods near such sources of air pollution also tend to be lower in income than people living elsewhere. Numerous studies evaluating the

demographics and socioeconomic status of populations or schools near roadways have found that they include a greater percentage of minority residents, as well as lower SES (indicated by variables such as median household income). Locations in these studies include Los Angeles, CA; Seattle, WA; Wayne County, MI; Orange County, FL; and the State of California.⁷¹² Such disparities may be due to multiple factors.⁷¹³

People with low SES often live in neighborhoods with multiple stressors and health risk factors, including reduced health insurance coverage rates, higher smoking and drug use rates, limited access to fresh food, visible neighborhood violence, and elevated rates of obesity and some diseases such as asthma, diabetes, and ischemic heart disease. Although questions remain, several studies find stronger associations between air pollution and health in locations with such chronic neighborhood stress, suggesting that populations in these areas may be more susceptible to the effects of air pollution.⁷¹⁴ Household-level

⁷¹¹ http://www.cdc.gov/asthma/most_recent_data.htm.

stressors such as parental smoking and relationship stress also may increase susceptibility to the adverse effects of air pollution.^{723 724}

More recently, three publications report nationwide analyses that compare the demographic patterns of people who do or do not live near major roadways.^{725 726 727} All three of these studies found that people living near major roadways are more likely to be minorities or low in SES. They also found that the outcomes of their analyses varied between regions within the U.S. However, only one such study looked at whether such conclusions were confounded by living in a location with higher population density and how demographics differ between locations nationwide. In general, it found that higher density areas have higher proportions of low income and minority residents.

We analyzed two national databases that allowed us to evaluate whether homes and schools were located near a major road and whether disparities in exposure may be occurring in these environments. The American Housing Survey (AHS) includes descriptive statistics of over 70,000 housing units across the nation. The study survey is conducted every two years by the U.S. Census Bureau. The second database we analyzed was the U.S. Department of Education's Common Core of Data,

which includes enrollment and location information for schools across the U.S.

In analyzing the 2009 AHS, we focused on whether or not a housing unit was located within 300 feet of "4-or-more lane highway, railroad, or airport."⁷²⁸ We analyzed whether there were differences between households in such locations compared with those in locations farther from these transportation facilities.⁷²⁹ We included other variables, such as land use category, region of country, and housing type. We found that homes with a nonwhite householder were 22–34 percent more likely to be located within 300 feet of these large transportation facilities than homes with white householders. Homes with a Hispanic householder were 17–33 percent more likely to be located within 300 feet of these large transportation facilities than homes with non-Hispanic householders. Households near large transportation facilities were, on average, lower in income and educational attainment, more likely to be a rental property and located in an urban area compared with households more distant from transportation facilities.

In examining schools near major roadways, we examined the Common Core of Data (CCD) from the U.S. Department of Education, which includes information on all public elementary and secondary schools and school districts nationwide.⁷³⁰ To determine school proximities to major roadways, we used a geographic information system (GIS) to map each school and roadways based on the U.S. Census's TIGER roadway file.⁷³¹ We found that minority students were overrepresented at schools within 200 meters of the largest roadways, and that schools within 200 meters of the largest roadways also had higher than expected numbers of students eligible for free or reduced-price lunches. For example, Black students represent 22 percent of students at schools located within 200 meters of a primary road, whereas Black students represent 17 percent of students in all U.S. schools. Hispanic

students represent 30 percent of students at schools located within 200 meters of a primary road, whereas Hispanic students represent 22 percent of students in all U.S. schools.

Overall, there is substantial evidence that people who live or attend school near major roadways are more likely to be of a minority race, Hispanic ethnicity, and/or low SES. The emission reductions from these final rules will likely result in widespread air quality improvements, but the impact on pollution levels in close proximity to roadways will be most direct. Thus, these final rules will likely help in mitigating the disparity in racial, ethnic, and economically based exposures.

B. Environmental Effects of Non-GHG Pollutants

(1) Visibility

Visibility can be defined as the degree to which the atmosphere is transparent to visible light.⁷³² Visibility impairment is caused by light scattering and absorption by suspended particles and gases. Visibility is important because it has direct significance to people's enjoyment of daily activities in all parts of the country. Individuals value good visibility for the well-being it provides them directly, where they live and work, and in places where they enjoy recreational opportunities. Visibility is also highly valued in significant natural areas, such as national parks and wilderness areas, and special emphasis is given to protecting visibility in these areas. For more information on visibility see the final 2009 p.m. ISA.⁷³³

EPA is working to address visibility impairment. Reductions in air pollution from implementation of various programs associated with the Clean Air Act Amendments of 1990 (CAAA) provisions have resulted in substantial improvements in visibility and will continue to do so in the future. Because trends in haze are closely associated with trends in particulate sulfate and nitrate due to the relationship between their concentration and light extinction, visibility trends have improved as emissions of SO₂ and NO_x have decreased over time due to air pollution

M.R. (2003) Relation between income, air pollution and mortality: a cohort study. *Canadian Med Assn J* 169: 397–402.

⁷²⁸ This variable primarily represents roadway proximity. According to the Central Intelligence Agency's World Factbook, in 2010, the United States had 6,506,204 km or roadways, 224,792 km of railways, and 15,079 airports. Highways thus represent the overwhelming majority of transportation facilities described by this factor in the AHS.

regulations such as the Acid Rain Program.⁷³⁴

In the Clean Air Act Amendments of 1977, Congress recognized visibility's value to society by establishing a national goal to protect national parks and wilderness areas from visibility impairment caused by manmade pollution.⁷³⁵ In 1999, EPA finalized the regional haze program to protect the visibility in Mandatory Class I Federal areas.⁷³⁶ There are 156 national parks, forests and wilderness areas categorized as Mandatory Class I Federal areas.⁷³⁷ These areas are defined in CAA Section 162 as those national parks exceeding 6,000 acres, wilderness areas and memorial parks exceeding 5,000 acres, and all international parks which were in existence on August 7, 1977.

EPA has also concluded that PM_{2.5} causes adverse effects on visibility in other areas that are not targeted by the Regional Haze Rule, such as urban areas, depending on PM_{2.5} concentrations and other factors such as dry chemical composition and relative humidity (*i.e.*, an indicator of the water composition of the particles). EPA revised the PM_{2.5} standards in December 2012 and established a target level of protection that is expected to be met through attainment of the existing secondary standards for PM_{2.5}.

(2) Plant and Ecosystem Effects of Ozone

The welfare effects of ozone can be observed across a variety of scales, *i.e.* subcellular, cellular, leaf, whole plant, population and ecosystem. Ozone effects that begin at small spatial scales, such as the leaf of an individual plant, when they occur at sufficient magnitudes (or to a sufficient degree) can result in effects being propagated along a continuum to larger and larger spatial scales. For example, effects at the individual plant level, such as altered rates of leaf gas exchange, growth and reproduction, can, when widespread, result in broad changes in ecosystems, such as productivity, carbon storage, water cycling, nutrient cycling, and community composition.

Ozone can produce both acute and chronic injury in sensitive species depending on the concentration level and the duration of the exposure.⁷³⁸ In

those sensitive species,⁷³⁹ effects from repeated exposure to ozone throughout the growing season of the plant tend to accumulate, so that even low concentrations experienced for a longer duration have the potential to create chronic stress on vegetation.⁷⁴⁰ Ozone damage to sensitive species includes impaired photosynthesis and visible injury to leaves. The impairment of photosynthesis, the process by which the plant makes carbohydrates (its source of energy and food), can lead to reduced crop yields, timber production, and plant productivity and growth. Impaired photosynthesis can also lead to a reduction in root growth and carbohydrate storage below ground, resulting in other, more subtle plant and ecosystem impacts.⁷⁴¹ These latter impacts include increased susceptibility of plants to insect attack, disease, harsh weather, interspecies competition and overall decreased plant vigor. The adverse effects of ozone on areas with sensitive species could potentially lead to species shifts and loss from the affected ecosystems,⁷⁴² resulting in a loss or reduction in associated ecosystem goods and services. Additionally, visible ozone injury to leaves can result in a loss of aesthetic value in areas of special scenic significance like national parks and wilderness areas and reduced use of sensitive ornamentals in landscaping.⁷⁴³

The most recent Integrated Science Assessment (ISA) for Ozone presents more detailed information on how ozone affects vegetation and ecosystems.⁷⁴⁴ The ISA concludes that ambient concentrations of ozone are associated with a number of adverse welfare effects and characterizes the weight of evidence for different effects

associated with ozone.⁷⁴⁵ The ISA concludes that visible foliar injury effects on vegetation, reduced vegetation growth, reduced productivity in terrestrial ecosystems, reduced yield and quality of agricultural crops, and alteration of below-ground biogeochemical cycles are causally associated with exposure to ozone. It also concludes that reduced carbon sequestration in terrestrial ecosystems, alteration of terrestrial ecosystem water cycling, and alteration of terrestrial community composition are likely to be causally associated with exposure to ozone.

(3) Atmospheric Deposition

Wet and dry deposition of ambient particulate matter delivers a complex mixture of metals (*e.g.*, mercury, zinc, lead, nickel, aluminum, and cadmium), organic compounds (*e.g.*, polycyclic organic matter, dioxins, and furans) and inorganic compounds (*e.g.*, nitrate, sulfate) to terrestrial and aquatic ecosystems. The chemical form of the compounds deposited depends on a variety of factors including ambient conditions (*e.g.*, temperature, humidity, oxidant levels) and the sources of the material. Chemical and physical transformations of the compounds occur in the atmosphere as well as the media onto which they deposit. These transformations in turn influence the fate, bioavailability and potential toxicity of these compounds.

Adverse impacts to human health and the environment can occur when particulate matter is deposited to soils, water, and biota.⁷⁴⁶ Deposition of heavy metals or other toxics may lead to the human ingestion of contaminated fish, impairment of drinking water, damage to terrestrial, freshwater and marine ecosystem components, and limits to recreational uses. Atmospheric deposition has been identified as a key component of the environmental and human health hazard posed by several pollutants including mercury, dioxin and PCBs.⁷⁴⁷

⁷⁴⁵ The Ozone ISA evaluates the evidence associated with different ozone related health and welfare effects, assigning one of five "weight of evidence" determinations: causal relationship, likely to be a causal relationship, suggestive of a causal relationship, inadequate to infer a causal relationship, and not likely to be a causal relationship. For more information on these levels of evidence, please refer to Table II of the ISA.

The ecological effects of acidifying deposition and nutrient enrichment are detailed in the Integrated Science Assessment for Oxides of Nitrogen and Sulfur-Ecological Criteria.⁷⁴⁸ Atmospheric deposition of nitrogen and sulfur contributes to acidification, altering biogeochemistry and affecting animal and plant life in terrestrial and aquatic ecosystems across the United States. The sensitivity of terrestrial and aquatic ecosystems to acidification from nitrogen and sulfur deposition is predominantly governed by geology. Prolonged exposure to excess nitrogen and sulfur deposition in sensitive areas acidifies lakes, rivers and soils. Increased acidity in surface waters creates inhospitable conditions for biota and affects the abundance and biodiversity of fishes, zooplankton and macroinvertebrates and ecosystem function. Over time, acidifying deposition also removes essential nutrients from forest soils, depleting the capacity of soils to neutralize future acid loadings and negatively affecting forest sustainability. Major effects in forests include a decline in sensitive tree species, such as red spruce (*Picea rubens*) and sugar maple (*Acer saccharum*). In addition to the role nitrogen deposition plays in acidification, nitrogen deposition also leads to nutrient enrichment and altered biogeochemical cycling. In aquatic systems increased nitrogen can alter species assemblages and cause eutrophication. In terrestrial systems nitrogen loading can lead to loss of nitrogen-sensitive lichen species, decreased biodiversity of grasslands, meadows and other sensitive habitats, and increased potential for invasive species. For a broader explanation of the topics treated here, refer to the description in Chapter 8.1.2.3 of the RIA.

Building materials including metals, stones, cements, and paints undergo natural weathering processes from exposure to environmental elements (e.g., wind, moisture, temperature fluctuations, sunlight, etc.). Pollution can worsen and accelerate these effects. Deposition of PM is associated with both physical damage (materials damage effects) and impaired aesthetic qualities (soiling effects). Wet and dry deposition of PM can physically affect materials, adding to the effects of natural weathering processes, by potentially promoting or accelerating the corrosion

of metals, by degrading paints and by deteriorating building materials such as stone, concrete and marble.⁷⁴⁹ The effects of PM are exacerbated by the presence of acidic gases and can be additive or synergistic due to the complex mixture of pollutants in the air and surface characteristics of the material. Acidic deposition has been shown to have an effect on materials including zinc/galvanized steel and other metal, carbonate stone (as monuments and building facings), and surface coatings (paints).⁷⁵⁰ The effects on historic buildings and outdoor works of art are of particular concern because of the uniqueness and irreplaceability of many of these objects.

(4) Environmental Effects of Air Toxics

Emissions from producing, transporting and combusting fuel contribute to ambient levels of pollutants that contribute to adverse effects on vegetation. Volatile organic compounds, some of which are considered air toxics, have long been suspected to play a role in vegetation damage.⁷⁵¹ In laboratory experiments, a wide range of tolerance to VOCs has been observed.⁷⁵² Decreases in harvested seed pod weight have been reported for the more sensitive plants, and some studies have reported effects on seed germination, flowering and fruit ripening. Effects of individual VOCs or their role in conjunction with other stressors (e.g., acidification, drought, temperature extremes) have not been well studied. In a recent study of a mixture of VOCs including ethanol and toluene on herbaceous plants, significant effects on seed production, leaf water content and photosynthetic efficiency were reported for some plant species.⁷⁵³

Research suggests an adverse impact of vehicle exhaust on plants, which has in some cases been attributed to aromatic compounds and in other cases to nitrogen oxides.^{754 755 756}

C. Emissions Inventory Impacts

As described in Section VII, the agencies conducted two analyses for these rules using DOT's CAFE model and EPA's MOVES model, relative to different reference cases (i.e., different baselines). The agencies used EPA's MOVES model to estimate the non-GHG impacts for tractor-trailers (including the engine that powers the vehicle) and vocational vehicles (including the engine that powers the vehicle). For heavy-duty pickups and vans, the agencies performed separate analyses using the CAFE model (included in NHTSA's "Method A;" See Section VI) and the MOVES model (included in EPA's "Method B;" See Section VI) to estimate non-GHG emissions from these vehicles. For these methods, the agencies analyzed the impact of the rules relative to two different reference cases—flat and dynamic. The flat baseline projects very little improvement in new vehicles in the absence of new Phase 2 standards. In contrast, the dynamic baseline projects more significant improvements in vehicle fuel efficiency. The agencies considered both reference cases. The results for all of the regulatory alternatives relative to both reference cases, derived via the same methodologies discussed in Section VII of the Preamble, are presented in Section X of the Preamble.

For brevity, a subset of these analyses are presented in this section and the reader is referred to both Chapter 11 of the RIA and NHTSA's FEIS Chapters 3, 4 and 5 for complete sets of these analyses. In this section, Method A is presented for the final standards, relative to both the dynamic baseline (Alternative 1b) and the flat baseline (Alternative 1a). Method B is presented for the final standards, relative only to the flat baseline.

The following subsections summarize two slightly different analyses of the annual non-GHG emissions reductions expected from these standards. Section VIII.A.(1) presents the impacts of the

final rules on non-GHG emissions using the analytical Method A, relative to two different reference cases—flat and dynamic. Section VIII.A.(2) presents the impacts of these standards, relative to the flat reference case only, using the MOVES model for all heavy-duty vehicle categories.

(1) Impacts of the Final Rules Using Analysis Method A

(a) Calendar Year Analysis

(i) Upstream Impacts of the Final Program

Increasing efficiency in heavy-duty vehicles will result in reduced fuel demand and, therefore, reductions in the emissions associated with all

processes involved in getting petroleum to the pump. Both Method A and Method B project these impacts for fuel consumed by vocational vehicles and combination tractor-trailers, using EPA's MOVES model. See Section VII.A. for the description of this methodology. To project these impacts for fuel consumed by HD pickups and vans, Method A used similar calculations and inputs applicable to the CAFE model, as discussed above in Section VI. More information on the development of the emission factors used in this analysis can be found in Chapter 5 of the RIA.

The following two tables summarize the projected upstream emission impacts of the final program on both criteria pollutants and air toxics from

the heavy-duty sector, relative to Alternative 1b (dynamic baseline conditions under the No-Action Alternative) and Alternative 1a (flat baseline conditions under the No-Action Alternative), using analysis method A. Using either No-Action Alternative shows decreases in upstream emissions of all criteria pollutants, precursors, and air toxics; using Alternative 1a as the reference point attributes more of the emission reduction to the standards. Note that the rule is projected, in all analyses, of reducing emissions of NO_x, contrary to implications in some of the public comments that fuel efficiency/GHG controls come at the expense of increased NO_x emissions.

(ii) Downstream Impacts of the Final Program

For vocational vehicles and tractor-trailers, the agencies used the MOVES model to determine non-GHG emissions inventories. The improvements in engine efficiency and road load, the increased use of APUs, and VMT

rebound were included in the MOVES analysis. For NHTSA's Method A analysis, presented in this section, the DOT CAFE model was used for HD pickups and vans. Further information about DOT's CAFE model is available in Section VI.C and Chapter 10 of the RIA. The following two tables summarize the

projected downstream emission impacts of the final program on both criteria pollutants and air toxics from the heavy-duty sector, relative to Alternative 1b and Alternative 1a, using analysis Method A. Using either baseline shows a reduction in all criteria pollutants and air toxics—except for 1,3-Butadiene,

and CY2025 levels of acrolein, which show small increases in downstream emissions.

(iii) Total Impacts of the Final Program

The following two tables summarize the projected upstream emission impacts of the final program on both

criteria pollutants and air toxics from the heavy-duty sector, relative to Alternative 1b and Alternative 1a, using analysis Method A. Under both baselines, Method A predicts a decrease

in total emissions by calendar year 2050, but the amount attributable to the standards is larger using the flat baseline than the dynamic baseline.

TABLE VIII-5—ANNUAL TOTAL IMPACTS (UPSTREAM AND DOWNSTREAM) OF CRITERIA POLLUTANTS AND AIR TOXICS FROM HEAVY-DUTY SECTOR IN CALENDAR YEARS 2025, 2040 AND 2050—FINAL PROGRAM VS. ALT 1b USING ANALYSIS METHOD A^a

(b) Model Year Lifetime Analysis

Table VIII–7 shows the lifetime Non-GHG reductions for model years 2018–2029 attributable to the standards using Method A relative to both No-Action Alternatives. For NO_x, approximately

half of the emission reductions are downstream and half are upstream. However, for PM_{2.5} and SO_x proportionally more of the emission reductions are attributable to upstream emission reductions than to downstream emission reductions. A

similar pattern emerges as with single calendar year snapshots; more emission reductions are attributable to the standards using the 1a baseline as the reference point than by using the 1b baseline as the reference point.

TABLE VIII–7—LIFETIME NON-GHG REDUCTIONS USING ANALYSIS METHOD A—SUMMARY FOR MODEL YEARS 2018–2029
[U.S. Short Tons]^a

NO-action alternative (baseline)	Final program	
	1b (Dynamic)	1a (Flat)

^bPM_{2.5} from tire wear and brake wear are included.

(2) Impacts of the Final Rules Using Analysis Method B

(a) Calendar Year Analysis

(i) Upstream Impacts of the Final Program

Increasing efficiency in heavy-duty vehicles will result in reduced fuel demand and, therefore, reductions in the emissions associated with all processes involved in getting petroleum to the pump. To project these impacts, Method B estimated the impact of reduced petroleum volumes on the extraction and transportation of crude

oil as well as the production and distribution of finished gasoline and diesel. For the purpose of assessing domestic-only emission reductions, it was necessary to estimate the fraction of fuel savings attributable to domestic finished gasoline and diesel and, of this fuel, what fraction is produced from domestic crude. Method B estimated the emissions associated with production and distribution of gasoline and diesel from crude oil based on emission factors in the “Greenhouse Gases, Regulated Emissions, and Energy used in Transportation” model (GREET)

developed by DOE’s Argonne National Laboratory. In some cases, the GREET values were modified or updated by the agencies to be consistent with the National Emission Inventory (NEI) and emission factors from MOVES. Method B estimated the projected corresponding changes in upstream emissions using the same tools originally created for the Renewable Fuel Standard 2 (RFS2) rulemaking analysis,⁷⁵⁷ used in the LD

⁷⁵⁷ U.S. EPA. Draft Regulatory Impact Analysis: Changes to Renewable Fuel Standard Program.

GHG rulemakings,⁷⁵⁸ HD GHG Phase 1,⁷⁵⁹ and updated for the current analysis. More information on the development of the emission factors

used in this analysis can be found in Chapter 5 of the RIA.

Table VIII–8 summarizes the projected upstream emission impacts of the final program on both criteria pollutants and air toxics from the heavy-

duty sector, relative to Alternative 1a, using analysis Method B. The comparable estimates relative to Alternative 1b are presented in Section VIII.C.(1).

TABLE VIII–8—ANNUAL UPSTREAM IMPACTS ON CRITERIA POLLUTANTS AND AIR TOXICS FROM HEAVY-DUTY SECTOR IN CALENDAR YEARS 2025, 2040 AND 2050—FINAL PROGRAM VS. ALT 1a USING ANALYSIS METHOD B^a

^aFor an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

(ii) Downstream Impacts of the Final Program

The final program will impact the downstream emissions of non-GHG pollutants. These pollutants include oxides of nitrogen (NO_x), oxides of sulfur (SO_x), volatile organic compounds (VOC), carbon monoxide (CO), fine particulate matter (PM_{2.5}), and air toxics. The agencies expect reductions in downstream emissions of NO_x, PM_{2.5}, VOC, SO_x, CO, and air toxics. Much of these estimated net reductions are a result of the agencies' anticipation of increased use of auxiliary power units (APUs) in combination tractors during extended idling; APUs emit these pollutants at a lower rate than on-road engines during extended idle operation, with the exception of PM_{2.5}. As discussed in

Section III.C.3, EPA is adopting Phase 1 and Phase 2 requirements to control PM_{2.5} emissions from APUs installed in new tractors and therefore, eliminate the unintended consequence of increased PM_{2.5} emissions from increased APU use.

Additional reductions in tailpipe emissions of NO_x and CO and refueling emissions of VOC will be achieved through improvements in engine efficiency and reduced road load (improved aerodynamics and tire rolling resistance), which reduces the amount of work required to travel a given distance and increases fuel economy. For vehicle types not affected by road load improvements, such as HD pickups and vans⁷⁶⁰, non-GHG emissions will increase very slightly due to VMT rebound. In addition, brake wear and tire wear emissions of PM_{2.5} will also

increase very slightly due to VMT rebound. The agencies estimate that downstream emissions of SO_x will be reduced, because they are roughly proportional to fuel consumption.

For vocational vehicles and tractor-trailers, the agencies used MOVES to determine non-GHG emissions impacts of the final rules, relative to the flat baseline (Alternative 1a) and the dynamic baseline (Alternative 1b). The improvements in engine efficiency and road load, the increased use of APUs, and VMT rebound were included in the MOVES analysis. For this analysis, Method B also used the MOVES model for HD pickups and vans.

The downstream criteria pollutant and air toxics impacts of the final program, relative to Alternative 1a, using analysis Method B, are presented in Table VIII–9.

^bPM_{2.5} from tire wear and brake wear are included.

As noted above, EPA is adopting Phase 1 and Phase 2 requirements to control PM_{2.5} emissions from APUs installed in new tractors. In the NPRM, EPA projected an unintended increase in downstream PM_{2.5} emissions because engines powering APUs are currently required to meet less stringent PM standards (40 CFR 1039.101) than on-road engines (40 CFR 86.007–11) and

because the increase in emissions from APUs more than offset the reduced tailpipe emissions from improved engine efficiency and road load. However, with the new requirements for APUs, the final program is projected to lead to reduced downstream PM_{2.5} emissions of 462 tons in 2040 and 580 tons in 2050 (Table VIII–9). The net reductions in national PM_{2.5} emissions

from the requirements for APUs are 927 tons and 1,114 tons in 2040 and 2050, respectively (Table VIII–10). See Section III.C.3 of the Preamble for additional details on EPA's PM emission standards for APUs. The development of APU emission rates with PM control is documented in a memorandum to the docket.⁷⁶¹

Note:

^aFor an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

It is worth noting that the emission reductions shown in Table VIII–9 are not incremental to the emissions reductions projected in the Phase 1 rulemaking. This is because, as described in Sections III.D.(1).a of the Preamble, the agencies have revised their assumptions about the adoption rate of APUs. This final rule assumes that without the Phase 2 program (*i.e.*,

in the Phase 2 baselines), the APU adoption rate will be 9 percent for model years 2010 and later. EPA conducted an analysis to estimate the combined emissions impacts of the Phase 1 and the Phase 2 programs for NO_x, VOC, SO_x and PM_{2.5} in calendar year 2050 using MOVES2014a. The results are shown in Table VIII–11. For NO_x and PM_{2.5} only, we also estimated

the combined Phase 1 and Phase 2 downstream and upstream emissions impacts for calendar year 2025, and project that the two rules combined will reduce NO_x by up to 55,000 tons and PM_{2.5} by up to 33,000 tons in that year. For additional details, see Chapter 5 of the RIA.

(b) Model Year Lifetime Analysis

In addition to the annual non-GHG emissions reductions expected from the final rules, EPA estimated the combined (downstream and upstream) non-GHG impacts for the lifetime of the impacted vehicles. Table VIII–13 shows the fleet-wide reductions of NO_x, PM_{2.5} and SO_x from the final program, relative to Alternative 1a, through the lifetime ⁷⁶² of heavy-duty vehicles. For the lifetime non-GHG reductions by vehicle categories, see Chapter 5 of the RIA.

^bPM_{2.5} from tire wear and brake wear are included.

D. Air Quality Impacts of Non-GHG Pollutants

Changes in emissions of non-GHG pollutants due to these rules will impact air quality. Information on current air quality and the results of our air quality modeling of the projected impacts of these rules are summarized in the following section. Additional information is available in Chapter 6 of the RIA.

(1) Current Concentrations of Non-GHG Pollutants

Nationally, levels of PM_{2.5}, ozone, NO_x, SO_x, CO and air toxics are declining. ⁷⁶³ However, as of April 22, 2016, more than 125 million people lived in counties designated nonattainment for one or more of the NAAQS, and this figure does not include the people living in areas with a risk of exceeding a NAAQS in the future. ⁷⁶⁴ Many Americans continue to

⁷⁶³ U.S. EPA, 2011. Our Nation's Air: Status and Trends through 2010. EPA-454/R-12-001. February 2012. Available at: <http://www3.epa.gov/airtrends/2011/>.

⁷⁶⁴ Data come from Summary Nonattainment Area Population Exposure Report, current as of April 22, 2016 at: <https://www3.epa.gov/airquality/greenbk/popexp.html> and contained in Docket EPA-HQ-OAR-2014-0827.

be exposed to ambient concentrations of air toxics at levels which have the potential to cause adverse health effects. ⁷⁶⁵ In addition, populations who live, work, or attend school near major roads experience elevated exposure concentrations to a wide range of air pollutants. ⁷⁶⁶

(a) Particulate Matter

There are two primary NAAQS for PM_{2.5}: An annual standard (12.0 micrograms per cubic meter (µg/m³)) set in 2012 and a 24-hour standard (35 µg/m³) set in 2006, and two secondary NAAQS for PM_{2.5}: An annual standard (15.0 µg/m³) set in 1997 and a 24-hour standard (35 µg/m³) set in 2006.

There are many areas of the country that are currently in nonattainment for the annual and 24-hour primary PM_{2.5} NAAQS. In 2005 the EPA designated 39 nonattainment areas for the 1997 PM_{2.5} NAAQS. ⁷⁶⁷ As of April 22, 2016, more than 23 million people lived in the 7 areas that are still designated as nonattainment for the 1997 annual PM_{2.5} NAAQS. These PM_{2.5}

⁷⁶⁵ U.S. EPA. (2015) Summary of Results for the 2011 National-Scale Assessment. <https://www3.epa.gov/sites/production/files/2015-12/documents/2011-nata-summary-results.pdf>.

⁷⁶⁶ Health Effects Institute Panel on the Health Effects of Traffic-Related Air Pollution. (2010) Traffic-related air pollution: A critical review of the literature on emissions, exposure, and health effects. HEI Special Report 17. Available at <http://www.healtheffects.org/>.

⁷⁶⁷ 70 FR 19844 (April 14, 2005).

nonattainment areas are comprised of 33 full or partial counties. In December 2014 EPA designated 14 nonattainment areas for the 2012 annual PM_{2.5} NAAQS.⁷⁶⁸ In March 2015, EPA changed the initial designation from nonattainment to unclassifiable/attainment for four areas based on the availability of complete, certified 2014 air quality data showing these areas met the 2012 annual PM_{2.5} NAAQS. The EPA also changed the initial 2012 annual PM_{2.5} NAAQS designation from nonattainment to unclassifiable for the Louisville, Indiana-Kentucky area.⁷⁶⁹ As of April 22, 2016, 9 of these areas remain designated as nonattainment, and they are composed of 20 full or partial counties with a population of over 23 million. On November 13, 2009 and February 3, 2011, the EPA designated 32 nonattainment areas for the 2006 24-hour PM_{2.5} NAAQS.⁷⁷⁰ As of April 22, 2016, 16 of these areas remain designated as nonattainment for the 2006 24-hour PM_{2.5} NAAQS, and they are composed of 46 full or partial counties with a population of over 32 million. In total, there are currently 24 PM_{2.5} nonattainment areas with a population of more than 39 million people.⁷⁷¹

The EPA has already adopted many mobile source emission control programs that are expected to reduce ambient PM concentrations. As a result of these and other federal, state and local programs, the number of areas that fail to meet the PM_{2.5} NAAQS in the future is expected to decrease. However, even with the implementation of all current state and federal regulations, there are projected to be counties violating the PM_{2.5} NAAQS well into the future. States will need to meet the 2006 24-hour standards in the 2015–2019 timeframe and the 2012 primary annual standard in the 2021–2025 timeframe. The emission reductions and improvements in ambient PM_{2.5} concentrations from this action, which will take effect as early as model year 2018, will be helpful to states as they

work to attain and maintain the PM_{2.5} NAAQS.⁷⁷² The standards can assist areas with attainment dates in 2018 and beyond in attaining the NAAQS as expeditiously as practicable and may relieve areas with already stringent local regulations from some of the burden associated with adopting additional local controls.

(b) Ozone

The primary and secondary NAAQS for ozone are 8-hour standards with a level of 0.07 ppm. The most recent revision to the ozone standards was in 2015; the previous 8-hour ozone primary standard, set in 2008, had a level of 0.075 ppm. Final nonattainment designations for the 2008 ozone standard were issued on April 30, 2012, and May 31, 2012.⁷⁷³ As of April 22, 2016, there were 44 ozone nonattainment areas for the 2008 ozone NAAQS, composed of 216 full or partial counties, with a population of more than 120 million. In addition, EPA plans to finalize nonattainment areas for the 2015 ozone NAAQS in October 2017.

States with ozone nonattainment areas are required to take action to bring those areas into attainment. The attainment date assigned to an ozone nonattainment area is based on the area's classification. The attainment dates for areas designated nonattainment for the 2008 8-hour ozone NAAQS are in the 2015 to 2032 timeframe, depending on the severity of the problem in each area. Nonattainment area attainment dates associated with areas designated for the 2015 NAAQS will be in the 2020–2037 timeframe, depending on the severity of the problem in each area.⁷⁷⁴

EPA has already adopted many emission control programs that are expected to reduce ambient ozone levels. As a result of these and other federal, state and local programs, 8-hour ozone levels are expected to improve in the future. However, even with the implementation of all current state and federal regulations, there are projected to be counties violating the ozone NAAQS well into the future. The emission reductions from this action, which will take effect as early as model year 2018, will be helpful to states as they work to attain and maintain the ozone NAAQS.⁷⁷⁵ The standards can assist areas with attainment dates in

2018 and beyond in attaining the NAAQS as expeditiously as practicable and may relieve areas with already stringent local regulations from some of the burden associated with adopting additional local controls.

(c) Nitrogen Dioxide

The EPA most recently completed a review of the primary NAAQS for NO₂ in January 2010. There are two primary NAAQS for NO₂: An annual standard (53 ppb) and a 1-hour standard (100 ppb). The EPA promulgated area designations in the **Federal Register** on February 17, 2012. In this initial round of designations, all areas of the country were designated as “unclassifiable/attainment” for the 2010 NO₂ NAAQS based on data from the existing air quality monitoring network. The EPA and state agencies are working to establish an expanded network of NO₂ monitors, expected to be deployed in the 2014–2017 time frame. Once three years of air quality data have been collected from the expanded network, the EPA will be able to evaluate NO₂ air quality in additional locations.^{776 777}

(d) Sulfur Dioxide

The EPA most recently completed a review of the primary SO₂ NAAQS in June 2010. The current primary NAAQS for SO₂ is a 1-hour standard of 75 ppb. The EPA finalized the initial area designations for 29 nonattainment areas in 16 states in a notice published in the **Federal Register** on August 5, 2013. In this first round of designations, EPA only designated nonattainment areas that were violating the standard based on existing air quality monitoring data provided by the states. The agency did not have sufficient information to designate any area as “attainment” or make final decisions about areas for which additional modeling or monitoring is needed (78 FR 47191, August 5, 2013). On March 2, 2015, the U.S. District Court for the Northern District of California accepted, as an enforceable order, an agreement between the EPA and Sierra Club and Natural Resources Defense Council to resolve litigation concerning the deadline for completing designations.⁷⁷⁸ The court's order directs the EPA to complete designations for all remaining

⁷⁶⁸ EPA 2014, Fact Sheet: Final Area Designations for the Annual Fine Particle Standard. <https://www3.epa.gov/pmdesignations/2012standards/final/20141218fs.pdf>.

⁷⁶⁹ <https://www3.epa.gov/pmdesignations/2012standards/final/20150331fs.pdf>.

⁷⁷⁰ 74 FR 58688 (November 13, 2009) and 76 FR 6056 (February 3, 2011).

⁷⁷¹ The 39 million total is calculated by summing, without double counting, the 1997, 2006 and 2012 PM_{2.5} nonattainment populations contained in the Summary Nonattainment Area Population Exposure report (<https://www3.epa.gov/airquality/greenbk/popexp.html>). If there is a population associated with more than one of the 1997, 2006 and 2012 nonattainment areas, and they are not the same, then the larger of the populations is included in the sum.

⁷⁷² The final Phase 2 trailer standards and PM controls for APUs begin with model year 2018.

⁷⁷⁷ U.S. Environmental Protection Agency (2013). Revision to Ambient Nitrogen Dioxide Monitoring Requirements. March 7, 2013. <http://www3.epa.gov/airquality/nitrogenoxides/pdfs/20130307fr.pdf>.

⁷⁷⁸ *Sierra Club v. McCarthy*, No. 3–13–cv–3953 (SI) (N.D. Cal. Mar. 2, 2015).

areas in the country in up to three additional rounds: The first round by July 2, 2016, the second round by December 31, 2017, and the final round by December 31, 2020.

(e) Carbon Monoxide

There are two primary NAAQS for CO: An 8-hour standard (9 ppm) and a 1-hour standard (35 ppm). The primary NAAQS for CO were retained in August 2011. There are currently no CO nonattainment areas; as of September 27, 2010, all CO nonattainment areas have been redesignated to attainment.

The past designations were based on the existing community-wide monitoring network. EPA is making changes to the ambient air monitoring requirements for CO. The new requirements are expected to result in approximately 52 CO monitors operating near roads within 52 urban areas by January 2015 (76 FR 54294, August 31, 2011).

(f) Diesel Exhaust PM

Because DPM is part of overall ambient PM and cannot be easily distinguished from overall PM, we do not have direct measurements of DPM in the ambient air. DPM concentrations are estimated using ambient air quality modeling based on DPM emission inventories. DPM emission inventories are computed as the exhaust PM emissions from mobile sources combusting diesel or residual oil fuel. DPM concentrations were recently estimated as part of the 2011 NATA.⁷⁷⁹ Areas with high concentrations are clustered in the Northeast, Great Lake States, California, and the Gulf Coast States and are also distributed throughout the rest of the U.S. The median DPM concentration calculated nationwide is 0.76 µg/m³. Half of the DPM can be attributed to heavy-duty diesel vehicles.

(g) Air Toxics

The most recent available data indicate that the majority of Americans continue to be exposed to ambient concentrations of air toxics at levels which have the potential to cause adverse health effects. The levels of air toxics to which people are exposed vary depending on where people live and work and the kinds of activities in which they engage, as discussed in detail in EPA's most recent Mobile

Source Air Toxics Rule.⁷⁸⁰ According to the National Air Toxic Assessment (NATA) for 2011, mobile sources were responsible for 50 percent of outdoor anthropogenic toxic emissions and were the largest contributor to cancer and noncancer risk from directly emitted pollutants.^{781 782} Mobile sources are also large contributors to precursor emissions which react to form air toxics. Formaldehyde is the largest contributor to cancer risk of all 71 pollutants quantitatively assessed in the 2011 NATA. Mobile sources were responsible for more than 25 percent of primary anthropogenic emissions of this pollutant in 2011 and are major contributors to formaldehyde precursor emissions. Benzene is also a large contributor to cancer risk, and mobile sources account for almost 80 percent of ambient exposure. Over the years, EPA has implemented a number of mobile source and fuel controls which have resulted in VOC reductions, which also reduced formaldehyde, benzene and other air toxic emissions.

(2) Impacts of the Rule on Projected Air Quality

Along with reducing GHGs, the Phase 2 standards also have an impact on non-GHG, criteria and air toxic pollutant, emissions. As shown above in Section VIII.C, the standards will impact exhaust emissions of these pollutants from vehicles and will also impact emissions that occur during the refining and distribution of fuel (upstream sources). Reductions in emissions of NO_x, VOC, PM_{2.5} and air toxics expected as a result of the Phase 2 standards will lead to improvements in air quality, specifically decreases in ambient concentrations of PM_{2.5}, ozone, NO₂ and air toxics, as well as better visibility and reduced deposition.

Emissions and air quality modeling decisions are made early in the analytical process because of the time and resources associated with full-scale photochemical air quality modeling. As a result, the inventories used in the air quality modeling and the benefits modeling are different from the final emissions inventories presented in

Section VIII.C. The air quality inventories and the final inventories are consistent in many ways, but there are some important differences. For example, in this final rulemaking, EPA is adopting Phase 1 and Phase 2 requirements to control PM_{2.5} emissions from APUs installed in new tractors, so we do not expect increases in downstream PM_{2.5} emissions from the Phase 2 program; however, the air quality inventories do not reflect these requirements and therefore show increases in downstream PM_{2.5} emissions. Chapter 5 of the RIA has more detail on the differences between the air quality and final inventories. The results of our air quality modeling of the criteria pollutant and air toxics impacts of the Phase 2 standards are summarized in the RIA and presented in more detail in Appendix 6A to the RIA.

IX. Economic and Other Impacts

This section presents the costs, benefits and other economic impacts of the Phase 2 standards. It is important to note that NHTSA's fuel consumption standards and EPA's GHG standards will both be in effect, and each will lead to average fuel efficiency increases and GHG emission reductions.

The net benefits of the Phase 2 standards consist of the effects of the program on:

- vehicle program costs (costs of complying with the vehicle CO₂ and fuel consumption standards)
- changes in fuel expenditures associated with reduced fuel use resulting from more efficient vehicles and increased fuel use associated with the "rebound" effect, both of which result from the program
- economic value of reductions in GHGs
- economic value of reductions in non-GHG pollutants
- costs associated with increases in noise, congestion, and crashes resulting from increased vehicle use
- savings in drivers' time from less frequent refueling
- benefits of increased vehicle use associated with the "rebound" effect
- economic value of improvements in U.S. energy security

The benefits and costs of these rules are analyzed using 3 percent and 7 percent discount rates, consistent with current OMB guidance.⁷⁸³ These rates

⁷⁸⁰ U.S. Environmental Protection Agency (2007). Control of Hazardous Air Pollutants from Mobile Sources; Final Rule. 72 FR 8434, February 26, 2007.

⁷⁸¹ U.S. EPA. (2015) 2011 NATA: Assessment Results. <https://www3.epa.gov/national-air-toxics-assessment/2011-nata-assessment-results>.

⁷⁸² NATA also includes estimates of risk attributable to background concentrations, which includes contributions from long-range transport, persistent air toxics, and natural sources; as well as secondary concentrations, where toxics are formed via secondary formation. Mobile sources substantially contribute to long-range transport and secondarily formed air toxics.

⁷⁸³ The range of Social Cost of Carbon (SC-CO₂) values uses several discount rates because the literature shows that the SC-CO₂ is quite sensitive to assumptions about the discount rate, and because no consensus exists on the appropriate rate to use in an intergenerational context (where costs and benefits are incurred by different generations). Refer to Section IX.F.1 for more information.

⁷⁷⁹ U.S. EPA (2015) 2011 National-Scale Air Toxics Assessment. <https://www3.epa.gov/national-air-toxics-assessment/2011-nata-assessment-results#emissions>.

are intended to represent consumers' preference for current over future consumption (3 percent), and the real rate of return on private investment (7 percent) which indicates the opportunity cost of capital. However, neither of these rates necessarily represents the discount rate that individual decision-makers use.

The program may also have other economic effects that are not included here. As discussed in Sections III through VI of this Preamble and in Chapter 2 of the RIA, the technology cost estimates developed here take into account the costs to hold other vehicle attributes, such as size and performance, constant. With these assumptions, and because welfare losses represent monetary estimates of how much buyers would have to be compensated to be made as well off as they would have been in the absence of this regulation,⁷⁸⁴ price increases for new vehicles measure the welfare losses to the vehicle buyers.⁷⁸⁵ If the full technology cost gets passed along to the buyer as an increase in price, the technology cost thus measures the primary welfare loss of the standards, including impacts on buyers. Increasing fuel efficiency would have to lead to other changes in the vehicles that buyers find undesirable for there to be additional welfare losses that are not included in the technology costs.

As the 2012–2016 and 2017–2025 light-duty GHG/CAFE rules discussed, if other vehicle attributes are not held constant, then the technology cost estimates do not capture the losses to vehicle buyers associated with these changes.⁷⁸⁶ The light-duty rules also

discussed other potential issues that could affect the calculation of the welfare impacts of these types of changes, such as aspects of buyers' behavior that might affect the demand for technology investments, uncertainty in buyers' investment horizons, and the rate at which truck owner's trade off higher vehicle purchase price against future fuel savings.

Where possible, we identify the uncertain aspects of these economic impacts and attempt to quantify them (e.g., sensitivity ranges associated with quantified and monetized GHG impacts; range of dollar-per-ton values to monetize non-GHG health benefits; uncertainty with respect to learning and markups). The agencies have examined the sensitivity of oil prices on fuel expenditures; results of this sensitivity analysis can be found in Chapter 8 of the RIA. NHTSA's EIS also characterizes the uncertainty in economic impacts associated with the HD national program. For other impacts, however, there is inadequate information to inform a thorough, quantitative assessment of uncertainty. EPA and NHTSA continue to work toward developing a comprehensive strategy for characterizing the aggregate impact of uncertainty in key elements of its analyses and we will continue to work to refine these uncertainty analyses in the future as time and resources permit.

This and other sections of the Preamble address Section 317 of the Clean Air Act on economic analysis. Section IX.L addresses Section 321 of the Clean Air Act on employment analysis. The total monetized benefits and costs of the program are summarized in Section IX.K for the final program and in Section X for all alternatives.

The agencies sought comment on numerous aspects of the analyses presented in this section, such as the potential omissions of costs or benefits, additional impacts of the standards on vehicle attributes and performance, and the quantification of uncertainty. Responses to comments on specific aspects of the analysis are addressed as appropriate in the relevant sections below, and in Sections III through VI of this Preamble as they relate to certain technologies. Further detail can be found in Section 11 of the RTC.

A. Conceptual Framework

The HD Phase 2 standards will implement both the 2007 Energy

Independence and Security Act requirement that NHTSA establish fuel efficiency standards for medium- and heavy-duty vehicles and the Clean Air Act requirement that EPA adopt technology-based standards to control pollutant emissions from motor vehicles and engines contributing to air pollution that endangers public health and welfare. NHTSA's statutory mandate is intended to further the agency's long-standing goals of reducing U.S. consumption and imports of petroleum energy to improve the nation's energy security.

From an economics perspective, government actions to improve our nation's energy security and to protect our nation from the potential threats of climate change address "externalities," or economic consequences of decisions by individuals and businesses that extend beyond those who make these decisions. For example, users of transportation fuels increase the entire U.S. economy's risk of having to make costly adjustments due to rapid increases in oil prices, but these users generally do not consider such costs when they decide to consume more fuel.

Similarly, consuming transportation fuel also increases emissions of greenhouse gases and other more localized air pollutants that occur when fuel is refined, distributed, and consumed. Some of these emissions increase the likelihood and severity of potential climate-related economic damages, and others cause economic damages by adversely affecting human health. The need to address these external costs and other adverse effects provides a well-established economic rationale that supports the statutory direction given to government agencies to establish regulatory programs that reduce the magnitude of these adverse effects at reasonable costs.

The Phase 2 standards will require manufacturers of new heavy-duty vehicles, including trailers (HDVs), to improve the fuel efficiency of the products that they produce. As HDV users purchase and operate these new vehicles, they will consume significantly less fuel, in turn reducing U.S. petroleum consumption and imports as well as emissions of GHGs and other air pollutants. Thus, as a consequence of the agencies' efforts to meet our statutory obligations to improve U.S. energy security and EPA's obligation to issue standards "to regulate emissions of the deleterious pollutant . . . from motor vehicles" that endangers public health and welfare,⁷⁸⁷

⁷⁸⁴ This approach describes the economic concept of compensating variation, a payment of money after a change that would make a consumer as well off after the change as before it. A related concept, equivalent variation, estimates the income change that would be an alternative to the change taking place. The difference between them is whether the consumer's point of reference is her welfare before the change (compensating variation) or after the change (equivalent variation). In practice, these two measures are typically very close together.

⁷⁸⁵ Indeed, it is likely to be an overestimate of the loss to the consumer, because the buyer has choices other than buying the same vehicle with a higher price; she could choose a different vehicle, or decide not to buy a new vehicle. The buyer would choose one of those options only if the alternative involves less loss than paying the higher price. Thus, the increase in price that the buyer faces would be the upper bound of loss of consumer welfare, unless there are other changes to the vehicle due to the fuel efficiency improvements that make the vehicle less desirable to consumers.

⁷⁸⁶ Environmental Protection Agency and Department of Transportation, "Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards; Final Rule," 75 FR 25324, May 7, 2010, especially Sections III.H.1 (25510–25513) and IV.G.6 (25651–25657); Environmental Protection Agency and Department of Transportation, "2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and

Corporate Average Fuel Economy Standards; Final Rule," 77 FR 62624, October 15, 2012, especially Sections III.H.1 (62913–62919) and IV.G.5.a (63102–63104).

⁷⁸⁷ *State of Massachusetts v. EPA*, 549 U.S. at 533.

the fuel efficiency and GHG emission standards will also reduce HDV operators' outlays for fuel purchases. These fuel savings are one measure of the final rule's effectiveness in promoting NHTSA's statutory goal of conserving energy, as well as EPA's obligation under section 202(a)(1) and (2) of the Clean Air Act to assess the cost of standards. Although these savings are not the agencies' primary motivation for adopting higher fuel efficiency standards, these substantial fuel savings represent significant additional economic benefits of these rules.

Potential savings in fuel costs appear to offer HDV buyer's strong incentives to pay higher prices for vehicles that feature technology or equipment that reduces fuel consumption. These potential savings also appear to offer HDV manufacturers similarly strong incentives to produce more fuel-efficient vehicles. Economic theory suggests that interactions between vehicle buyers and sellers in a normally-functioning competitive market would lead HDV manufacturers to incorporate all technologies that contribute to lower net costs into the vehicles they offer, and buyers to purchase them willingly. Nevertheless, many readily available technologies that appear to offer cost-effective increases in HDV fuel efficiency (when evaluated over their expected lifetimes using conventional discount rates) have not been widely adopted, despite their potential to repay buyers' initial investments rapidly.

This economic situation is commonly known as the "energy efficiency gap" or "energy paradox." This situation is perhaps more challenging to understand with respect to the heavy-duty sector versus the light-duty vehicle sector. Unlike light-duty vehicles—which are purchased and used mainly by individuals and households—the vast majority of HDVs are purchased and operated by profit-seeking businesses for which fuel costs represent a substantial operating expense. We asked for comments on our hypotheses about causes of the gap, as well as data or other information that can inform our understanding of why this situation seems to persist. The California Air Resources Board, CALSTART, Consumer Federation of America, Institute for Policy Integrity at NYU School of Law, and International Council on Clean Transportation supported, either in whole or in part, the agencies' arguments for potential barriers to market adoption. Caterpillar Inc. et al., Competitive Enterprise Institute (CEI), Randall Lutter, Brian Mannix, NAFA Fleet Management Association (NAFA), Owner-Operator

Independent Drivers Association (OIDA), Truck Renting and Leasing Association (TRALA), and Utility Trailer Manufacturing Company express skepticism or raise concerns about the agencies' discussion. The skeptical comments, discussed in more depth in context below, generally find it implausible that regulations can save money for profit-seeking businesses. If the savings were real, they argue, then private markets would have adopted these technologies without regulations; the agencies must therefore have exaggerated the benefits or underestimated the costs of the standards. Problems exist not in private market operations, they claim, but rather in the economic analysis of those operations.

The economic analysis of these standards is based on the engineering analysis of the costs and effectiveness of the technologies. The agencies have detailed their findings on costs and effectiveness in Preamble Sections III, IV, V, and VI, and RIA Chapter 2. If these cost and effectiveness estimates are correct, and if the agencies have not omitted key costs or benefits, then the efficiency gap exists, even if it seems implausible to some. As will be discussed further below, comments that raise issues with that technical analysis, such as concerns about maintenance and reliability costs of the technologies, present possible reasons that the gap is not as large as the agencies have found, and are discussed in the cost and effectiveness sections mentioned above. Comments that question the explanations provided for the gap without addressing the cost and effectiveness analyses do not provide evidence of an absence of the gap. Explaining why the gap exists is a separate and difficult challenge from observing the existence of the gap, because of the difficulties involved in developing tests of the different possible explanations. As discussed below, there is very little empirical evidence on behaviors that might lead to the gap, even while there continues to be substantial evidence, via the cost and effectiveness analysis, of the gap's existence. On the basis of that evidence, the agencies believe that a significant number of fuel efficiency improving technologies would remain far less widely adopted in the absence of these standards.

Economic research offers several possible explanations for why the prospect of these apparent savings might not lead HDV manufacturers and buyers to adopt technologies that would be expected to reduce HDV operating costs. Some of these explanations

involve failures of the HDV market for reasons other than the externalities caused by producing and consuming fuel. Examples include situations where information about the performance of fuel economy technologies is incomplete, costly to obtain, or available only to one party to a transaction (or "asymmetrical"), as well as behavioral rigidities in either the HDV manufacturing or HDV-operating industries, such as standardized or inflexibly administered operating procedures, or requirements of other regulations on HDVs. Examples that do not involve market failures include possible effects on the performance, reliability, carrying capacity, maintenance requirements of new technology under the demands of everyday use, or transaction or adjustment costs. We note again that these and other hypotheses are presented as potential explanations of the finding of an efficiency gap based on an engineering analysis. They are not themselves the basis for regulation.

In the HD Phase 1 rulemaking (which, in contrast to these standards, did not apply to trailers), and in the Phase 2 NPRM, the agencies raised various hypotheses that might explain this energy efficiency gap or paradox.

- Imperfect information in the new vehicle market: Information available to prospective buyers about the effectiveness of some fuel-saving technologies for new vehicles may be inadequate or unreliable. If reliable information on their effectiveness in reducing fuel consumption is unavailable or difficult to obtain, HDV buyers will understandably be reluctant to pay higher prices to purchase vehicles equipped with unproven technologies.

Some commenters argue that this explanation implies implausibly that the agencies have information that those with profit motives do not, and that EPA's SmartWay Program has already served the function of sharing public information with the private sector. Other commenters agree with the agencies that imperfect information is a potential market barrier.

As discussed in the NPRM, one common theme from recent research⁷⁸⁸

⁷⁸⁸ Klemick, Heather, Elizabeth Kopits, Keith Sargent, and Ann Wolverton (2015). "Heavy-Duty Trucking and the Energy Efficiency Paradox: Evidence from Focus Groups and Interviews." *Transportation Research Part A* 77: 154–166, Docket EPA–HQ–OAR–2014–0827; Roeth, Mike, Dave Kircher, Joel Smith, and Rob Swim (2013). "Barriers to the Increased Adoption of Fuel Efficiency Technologies in the North American On-Road Freight Sector." NACFE report for the International Council on Clean Transportation,

is the inability of HDV buyers to obtain reliable information about the fuel savings, reliability, and maintenance costs of technologies that improve fuel efficiency. See 80 FR 40436. In the trucking industry, the performance of fuel-saving technology is likely to depend on many firm-specific attributes, including the intensity of HDV use, the typical distance and routing of HDV trips, driver characteristics, road conditions, regional geography and traffic patterns. As a result, businesses that operate HDVs have strong preferences for testing fuel-saving technologies “in-house” because they are concerned that their patterns of vehicle use may lead to different results from those reported in published information. Businesses with less capability to do in-house testing often seek information from peers, yet often remain skeptical of its applicability due to differences in the nature of their operations.

- Imperfect information in the resale market: Buyers in the used vehicle market may not be willing to pay adequate premiums for more fuel efficient vehicles when they are offered for resale to ensure that buyers of new vehicles can recover the remaining value of their original investment in higher fuel efficiency. The prospect of an inadequate return on their original owners’ investments in higher fuel efficiency may contribute to the short payback periods that buyers of new vehicles appear to demand.⁷⁸⁹

CEI rejects this hypothesis, asserting that buyers in this market do consider the value of technologies on used vehicles; other commenters support this possibility.

The recent research cited above (Klemick et al. 2015, Roeth et al. 2013, Aarnink et al. 2012) found mixed evidence for imperfect information in the market for used HDVs. On the one hand, some studies noted that fuel-saving technology is often not appreciated in the used vehicle market,

because of imperfect information about its benefits, or greater mistrust of its performance among buyers in the used vehicle market than among buyers of new vehicles. When buyers of new vehicles considered features that would affect value in the secondary market, those features were rarely related to fuel economy. In addition, some used-vehicle buyers might have a larger “knowledge gap” than new-vehicle buyers. In other cases, the lack of interest might be due to the intended use of the used HDVs, which may not reward the presence of certain fuel-saving technologies. In other cases, however, fuel-saving technology can lead to a premium in the used market, as for instance to meet the more stringent requirements for HDVs operating in California.

- Principal-agent problems causing split incentives: An HDV buyer may not be directly responsible for its future fuel costs, or the individual who will be responsible for fuel costs may not participate in the HDV purchase decision. In these cases, the signal to invest in higher fuel efficiency normally provided by savings in fuel costs may not be transmitted effectively to HDV buyers, and the incentives of HDV buyers and fuel buyers will diverge, or be “split.” The trailers towed by heavy-duty tractors, which are typically not supplied by the tractor manufacturer or seller, present an obvious potential situation of split incentives that was not addressed in the HD Phase 1 rulemaking, but which may apply in this rulemaking. If there is inadequate pass-through of price signals from trailer users to their buyers, then low adoption of fuel-saving technologies may result.

CEI argues that, even if these split incentives existed, vehicle purchasers still might not invest in fuel-saving technologies due to capital constraints. As discussed below, capital constraints may be an issue for smaller companies, but they do not appear to be a significant concern for larger companies. Mr. Lutter provides a working paper⁷⁹⁰ in which the authors do not find a statistically significant or negative relationship when the box trailer has different ownership than the tractor, a result that does not support evidence of the split-incentives problem between tractors and trailers. As the papers below discuss, the split-incentives problem can take more forms than the difference in ownership

between tractors and box trailers examined in this comment.

Other recent research identifies split incentives, or principal-agent problems, as a potential barrier to technology adoption. For instance, Vernon and Meier (2012) estimate that 23 percent of trailers may be exposed to split incentives due to businesses that own and lease trailers to HDV operators not having an incentive to invest in trailer-specific fuel-saving technology.⁷⁹¹ They also estimate that 5 percent of HDV fuel use is subject to split incentives that arise when the firm paying fuel costs does not make the tractor investment decision (e.g., because a carrier subcontracts to an owner-operator but still pays for fuel). As CEI points out, in the case of a split incentive when the driver is not responsible for paying fuel costs, the owner is the principal who seeks fuel savings, and the driver is the agent with potentially low incentive to provide those savings; there are a number of potential sources of inefficiency in fuel use, though not all of them are expected to result in underinvestment in fuel-saving technologies. Vernon and Meier (2012) do not quantify the financial significance of these problems.

Klemick et al. (2015), Aarnink et al. (2012), and Roeth et al. (2013) provide mixed evidence on the severity of the split-incentive problem. Focus groups often identify diverging incentives between drivers and the decision-makers responsible for purchasing vehicles. Aarnink et al. (2012) and Roeth et al. (2013) cite examples of split incentives involving trailers and fuel surcharges, although the latter also cites other examples where these same issues do not lead to split incentives. In an effort to minimize problems that can arise from split incentives, many businesses that operate HDVs also train drivers in the use of specific technologies or to modify their driving behavior in order to improve fuel efficiency, while some also offer financial incentives to their drivers to conserve fuel. All of these options can help to reduce the split incentive problem.

- Uncertainty about future fuel cost savings: HDV buyers may be uncertain about future fuel prices, or about maintenance costs and reliability of some fuel efficiency technologies. In contrast, the costs of fuel-saving technologies are immediate. If buyers

⁷⁹¹ Vernon, David and Alan Meier (2012). “Identification and quantification of principal-agent problems affecting energy efficiency investments and use decisions in the trucking industry.” Energy Policy, 49(C), pp. 266–273, Docket EPA-HQ-OAR-2014-0827-0090.

are loss-averse, they may react to this uncertainty by underinvesting in technologies to improve fuel economy. In this situation, potential variability about buyers' expected returns on capital investments to achieve higher fuel efficiency may shorten the payback period—the time required to repay those investments—they demand in order to make them.

Various commenters support this hypothesis. The CEI draws on the experience of nitrogen oxides (NO_x) regulations from 2004 and 2007 to support its arguments. As discussed more below, the NO_x standards are unlikely to provide much, if any, precedential value for the GHG/fuel economy standards. Other commenters raise questions related to uncertainty about future costs for fuel and maintenance, as well as about the reliability of new technology that could result in costly downtime. Section IX.D. below discusses maintenance expenditures under these standards. These examples illustrate the problem of uncertain or unreliable information about the actual performance of fuel efficiency technology discussed above. Roeth et al. (2013) and Klemick et al. (2015) both document the short payback periods that HDV buyers require on their investments—usually about 2 years—which may be partly attributable to these uncertainties.

- **Adjustment and transactions costs:** Potential resistance to new technologies—stemming, for example, from drivers' reluctance or slowness to adjust to changes in the way vehicles operate—may slow or inhibit new technology adoption. If a conservative approach to new technologies leads HDV buyers to adopt them slowly, then successful new technologies will be adopted over time without market intervention, but only with potentially significant delays in achieving the fuel saving, environmental, and energy security benefits they offer. There also may be costs associated with training drivers to realize potential fuel savings enabled by new technologies, or with accelerating fleet operators' scheduled fleet turnover and replacement to hasten their acquisition of vehicles equipped with these technologies. These factors might present real resource costs to firms that are not reflected in a typical engineering analysis.

CEI argues that these costs are normal aspects of the innovation process, and competition continually drives firms to innovate in most industries. As discussed below, innovation is not always a continual and smooth response to competition as CEI suggests.

Klemick et al. (2015), Roeth et al. (2013), and Aarnink et al. (2012) provide some support for the view that adjustment and transactions costs may impede HDV buyers from investing in higher fuel efficiency. These studies note that HDV buyers are less likely to select new technology when it is not available from their preferred manufacturers. Some technologies are only available as after-market additions, which can add other costs to adopting them.

- **Driver acceptance of new equipment or technologies as a barrier to their adoption.** HDV driver turnover is high in the U.S., and businesses that operate HDVs are concerned about retaining their best drivers. Therefore, they may avoid technologies that require significant new training or adjustments in driver behavior.

NAFA Fleet Management Association states that the standards will increase pressure on already strained driver and technician resources. The agencies understand that the industry experiences a great deal of driver turnover; we do not know how the standards will affect that turnover. Changes to vehicles that require some changes in driver behavior may increase driver turnover. For instance, drivers who prefer manual transmissions may respond poorly to vehicles with automatic transmissions. On the other hand, the switch to automatic transmissions may facilitate entry of new drivers who no longer need to learn as much about shifting.

For some technologies that can be used to meet these standards, such as automatic tire inflation systems, training costs are likely to be minimal. Other technologies, such as stop-start systems, may require drivers to adjust their expectations about vehicle operation, and it is difficult for the agencies to anticipate how drivers will respond to such changes.⁷⁹²

- **Constraints on access to capital for investment.** If buyers of new vehicles have limited funds available, then they must choose between investing in fuel-saving technology and other vehicle technologies or attributes.

CEI states that investments require tradeoffs: Investment in fuel economy crowds out other investments. There would be tradeoffs in purchasing choices if capital markets are constrained, and fuel-saving

technologies do not provide returns sufficient to achieve the hurdle rates that the buyers require. Klemick et al. (2015) did not find capital constraints to be a problem for the medium- and large-sized businesses participating in their study. On the other hand, Roeth et al. (2013) noted that access to capital can be a significant challenge to smaller or independent businesses, and that price is always a concern to buyers. Section XIV.D. discusses the agencies' outreach to small businesses to learn about their special circumstances. These are reflected in various flexibilities for small businesses in the regulations.

- **"Network externalities,"** where the benefits to new users of a technology depend on how many others have already adopted it. If the value of a technology increases with increasing adoption, then it can be difficult for the adoption process to begin: Each potential adopter has an incentive to wait for others to adopt before making the investment. If all adopters wait for others, then adoption may not happen.

One example where network externalities seem likely to arise is the market for natural gas-fueled HDVs: The limited availability of refueling stations may reduce potential buyers' willingness to purchase natural gas-fueled HDVs, while the small number of such HDVs in use does not provide sufficient economic incentive to construct more natural gas refueling stations. Some businesses that operate HDVs may also be concerned about the difficulty in locating repair facilities or replacement parts, such as single-wide tires, wherever their vehicles operate. When a technology has been widely adopted, then it is likely to be serviceable even in remote or rural places, but until it becomes widely available, its early adopters may face difficulties with repairs or replacements. By accelerating the widespread adoption of these technologies, these standards may assist in overcoming these difficulties.

Consumer Federation of America states that network externalities are a potentially important barrier to adoption of fuel-saving technologies.

- **First-mover disadvantage.** Many manufacturers prefer to observe the market and follow other manufacturers rather than be the first to market with a specific technology. The "first-mover disadvantage" has been recognized in other research where the "first-mover" pays a higher proportion of the costs of developing technology, but loses the long-term advantage when other

⁷⁹² The distinction between simply requiring drivers (or mechanics) to adjust their expectations and compromises in vehicle performance or utility is subtle. While the former may not impose significant compliance costs in the long run, the latter would represent additional economic costs of complying with the standard.

businesses follow quickly.⁷⁹³ In this way, there may be barriers to innovation on the supply side that result in lower adoption rates of fuel-efficiency technology than would be optimal.

Several commenters support the existence of the first-mover disadvantage. Roeth et al. (2013) noted that HDV buyers often prefer to have technology or equipment installed by their favored original equipment manufacturers. However, some technologies may not be available through these preferred sources, or may be available only as after-market installations from third parties (Aarnink et al. 2012, Roeth et al. 2013). Manufacturers may be hesitant to offer technologies for which there is not strong demand, especially if the technologies require significant research and development expenses and other costs of bringing the technology to a market of uncertain demand. Roeth et al. (2013) noted that it can take years, and sometimes as much as a decade, for a specific technology to become available from all manufacturers.

As mentioned above, the Competitive Enterprise Institute argues that EPA regulations on nitrogen oxides (NO_x) and other pollutants from heavy duty engines in the 2000s hindered development of fuel-saving technologies, in part because the technologies increased fuel consumption, and in part because, if manufacturers invested in NO_x controls, they could not invest in reducing fuel consumption. The agencies do not find these potential explanations compelling. Most obviously, the NO_x and other standards do not provide a useful analogy for industry response to the GHG/fuel efficiency standards, because those standards imposed costs without returning fuel savings to operators. In addition, as the discussion of technology cost and effectiveness indicates, technologies that are not in widespread use seem to be available to reduce fuel consumption with reasonable payback periods. Finally, the agencies consider it possible to reduce NO_x in the presence of GHG controls, and to reduce GHG emissions in the presence of NO_x controls; the cost analysis for this rulemaking accounts for

achieving NO_x emissions standards. See also RTC Sections 11.2.2.3 and 11.7.2.

In summary, the agencies recognize that businesses that operate HDVs are under competitive pressure to reduce operating costs, which should compel HDV buyers to identify and rapidly adopt cost-effective fuel-saving technologies. Outlays for labor and fuel generally constitute the two largest shares of HDV operating costs, depending on the price of fuel, distance traveled, type of HDV, and commodity transported (if any), so businesses that operate HDVs face strong incentives to reduce these costs.^{794 795}

However, the relatively short payback periods that buyers of new HDVs appear to require suggest that some combination of the factors cited above impedes this process. Markets for both new and used HDVs may face these problems, although it is difficult to assess empirically the degree to which they actually do. Even if the benefits from widespread adoption of fuel-saving technologies exceed their costs, their use may remain limited or spread slowly because their early adopters bear a disproportionate share of those costs. In this case, as CFA says in its comments, these standards may help to overcome such barriers by ensuring that these measures will be widely adopted.

Providing information about fuel-saving technologies, offering incentives for their adoption, and sharing HDV operators' real-world experiences with their performance through voluntary programs such as EPA's SmartWay Transport Partnership should assist in the adoption of new cost-saving technologies. Nevertheless, other barriers that impede the diffusion of new technologies are likely to remain. Buyers who are willing to experiment with new technologies expect to find cost savings, but those savings may be difficult to verify or replicate. As noted previously, because benefits from employing these technologies are likely to vary with the characteristics of individual routes and traffic patterns, buyers of new HDVs may find it difficult to identify or verify the effects of fuel-saving technologies in their operations. Risk-averse buyers may also avoid new technologies out of concerns over the possibility of inadequate

returns on their investments, or with other possible adverse impacts.

As various commenters note, competitive pressures in the HDV freight transport industry can provide a strong incentive to reduce fuel consumption and improve environmental performance. Nevertheless, HDV manufacturers may delay in investing in the development and production of new technologies, instead waiting for other manufacturers to bear the initial risks of those investments. In addition, not every HDV operator has the requisite ability or interest to access and utilize the technical information, or the resources necessary to evaluate this information within the context of his or her own operations.

As discussed previously, whether the technologies available to improve HDVs' fuel efficiency would be adopted widely in the absence of the program is challenging to assess. To the extent that these technologies would be adopted in its absence, neither their costs nor their benefits should be attributed to the program.

The agencies will continue to explore reasons for the slow adoption of readily available and apparently cost-effective technologies for improving fuel efficiency.

B. Vehicle-Related Costs Associated With the Program

(1) Technology Cost Methodology

(a) Direct Manufacturing Costs

The direct manufacturing costs (DMCs) used throughout this analysis are derived from several sources. Many of the tractor, vocational and trailer DMCs can be sourced to the Phase 1 rule which, in turn, were sourced largely from a contracted study by ICF International for EPA.⁷⁹⁶ We have updated those costs by converting them to 2013 dollars, as described in Section IX.B.1.e below, and by continuing the learning effects described in the Phase 1 rule and in Section IX.B.1.c below. The new tractor, vocational and trailer costs can be sourced to a more recent study conducted by Tetra Tech under contract to NHTSA.⁷⁹⁷ The cost methodology used by Tetra Tech was to estimate retail costs and work backward from there to derive a DMC for each technology. The agencies did not agree with the approach used by Tetra Tech

⁷⁹³ Blumstein, Carl and Margaret Taylor (2013). "Rethinking the Energy-Efficiency Gap: Producers, Intermediaries, and Innovation," Energy Institute at Haas Working Paper 243, University of California at Berkeley, Docket EPA-HQ-OAR-2014-0827-0075; Tirole, Jean (1998). *The Theory of Industrial Organization*. Cambridge, MA: MIT Press, pp.400, 402, Docket EPA-HQ-OAR-2014-0827-0089. This first-mover disadvantage must be large enough to overcome the potential incentive for first movers to earn unusually high but temporary profit levels.

to move from retail cost to DMC as the approach was to simply divide retail costs by 2 and use the result as a DMC. Our research, discussed below, suggests that a divisor of 2 is too high. Therefore, where we have used a Tetra Tech derived retail estimate, we have divided by our researched markups to arrive at many of the DMCs used in this analysis. In this way, the agencies have used an approach consistent with past GHG/CAFE/fuel consumption rules by dividing estimated retail prices by our estimated retail price equivalent (RPE) markups to derive an appropriate DMC for each technology. We describe our RPEs in Section IX.B.1.b, below. Importantly, nearly all of the technology costs used in the final analysis are identical to those used in the proposal, except for updating those costs from 2012 dollars to 2013 dollars. Notable changes are the costs for waste heat recovery and the use of new technologies (*e.g.*, APU with DPF, battery powered APU and a different stop-start technology on vocational vehicles) that were not considered in the proposal. We describe these changes in Chapter 2.11 of the RIA.

Importantly, technology costs differ from package costs which include adoption rates. Package costs have changed more significantly due to changes to the adoption rates as described throughout the earlier sections of this Preamble and briefly below in Section IX.B.1.(d).

For HD pickups and vans, we have similarly used costs from the proposal except for the updating to 2013 dollars. As explained in the proposal, we relied primarily on the Phase 1 rule and the recent light-duty 2017–2025 model year rule since most technologies expected on these vehicles are, in effect, the same as those used on light-duty pickups. Many of those technology DMCs are based on cost teardown studies which the agencies consider to be the most robust method of cost estimation. However, because most of the HD versions of those technologies are expected to be more costly than their light-duty counterparts, we have scaled upward most of the light-duty DMCs for this analysis. We have also used some costs developed under contract to NHTSA by Tetra Tech.⁷⁹⁸

Importantly, in our methodology, all technologies are treated as being sourced from a supplier rather than being developed and produced in-house. As a result, some portion of the

total indirect costs of making a technology or system—those costs incurred by the supplier for research, development, transportation, marketing etc.—are contained in the sales price to the engine and/or vehicle/trailer manufacturer (*i.e.*, the original equipment manufacturer (OEM)). That sale price paid by the OEM to the supplier is the DMC we estimate.

We present the details—sources, DMC values, scaling from light-duty values, markups, learning effects, adoption rates—behind all our costs in Chapter 2 of the RIA.

(b) Indirect Costs

To produce a unit of output, engine and truck manufacturers incur direct and indirect costs. Direct costs include cost of materials and labor costs. Indirect costs are all the costs associated with producing the unit of output that are not direct costs—for example, they may be related to production (such as research and development [R&D]), corporate operations (such as salaries, pensions, and health care costs for corporate staff), or selling (such as transportation, dealer support, and marketing). Indirect costs are generally recovered by allocating a share of the costs to each unit of good sold. Although it is possible to account for direct costs allocated to each unit of good sold, it is more challenging to account for indirect costs allocated to a unit of goods sold. To make a cost analysis process more feasible, markup factors, which relate total indirect costs to total direct costs, have been developed. These factors are often referred to as retail price equivalent (RPE) multipliers.

While the agencies have traditionally used RPE multipliers to estimate indirect costs, in recent GHG/CAFE/fuel consumption rules RPEs have been replaced in the primary analysis with indirect cost multipliers (ICMs). ICMs differ from RPEs in that they attempt to estimate not all indirect costs incurred to bring a product to point of sale, but only those indirect costs that change as a result of a government action or regulatory requirement. As such, some indirect costs, notably health and retirement benefits of retired employees, among other indirect costs, will not be expected to change due to a government action and, therefore, the portion of the RPE that covered those costs does not change.

Further, the ICM is not a “one-size-fits-all” markup as is the traditional RPE. With ICMs, higher complexity technologies like hybridization or moving from a manual to automatic transmission may require higher

indirect costs—more research and development, more integration work, etc.—suggesting a higher markup. Conversely, lower complexity technologies like reducing friction or adding passive aero features may require fewer indirect costs thereby suggesting a lower markup.

Notably, ICMs are also not a simple multiplier as are traditional RPEs. The ICM is broken into two parts—warranty related and non-warranty related costs. The warranty related portion of the ICM is relatively small while the non-warranty portion represents typically over 95 percent of indirect costs. These two portions are applied to different DMC values to arrive at total costs (TC). The warranty portion of the markup is applied to a DMC that decreases year-over-year due to learning effects (described below in Section IX.B.1.c).⁷⁹⁹ As learning effects decrease the DMC with production volumes, it makes sense that warranty costs will decrease since those parts replaced under warranty should be less costly. In contrast, the non-warranty portion of the markup is applied to a static DMC year-over-year resulting in static indirect costs. This is logical since the production plants and transportation networks and general overhead required to build parts, market them, deliver them and integrate them into vehicles do not necessarily decrease in cost year-over-year. Because the warranty and non-warranty portions of the ICM are applied differently, one cannot compare the markup itself to the RPE to determine which markup will result in higher indirect cost estimates, at least in the time periods typically considered in our rules (four to ten years).

In the NPRM, the agencies expressed concern that some potential costs associated with this rulemaking may not be adequately captured by our ICMs. ICMs are estimated based on a few specific technologies and these technologies may not be representative of the changes actually made to meet the requirements. We requested and received comment on this issue. Specifically, some commenters argued that we had underestimated costs associated with R&D and costs associated with our compliance programs, both of which are indirect costs. However, we address those indirect costs separately because GHG-related R&D and GHG-related

⁷⁹⁸ Schubert, R., Chan, M., Law, K. (2015). Commercial Medium- and Heavy-Duty (MD/HD) Truck Fuel Efficiency Cost Study. Washington, DC: National Highway Traffic Safety Administration.

⁷⁹⁹ We note that the labor portion of warranty repairs does not decrease due to learning. However, we do not have data to separate this portion and so we apply learning to the entire warranty cost. Because warranty costs are a small portion of overall indirect costs, this has only a minor impact on the analysis.

compliance were not part of the retail price equivalent markups upon which our indirect cost multipliers are based. We discuss these R&D and compliance costs more below and in Chapter 7 of the RIA.

We provide more details on our ICM approach and the markups used for each technology in Chapter 2.12 of the RIA.

(c) Learning Effects on Direct and Indirect Costs

For some of the technologies considered in this analysis, manufacturer learning effects will be expected to play a role in the actual end costs. The “learning curve” or “experience curve” describes the reduction in unit production costs as a function of accumulated production volume. In theory, the cost behavior it describes applies to cumulative production volume measured at the level of an individual manufacturer, although it is often assumed—as both agencies have done in past regulatory analyses—to apply at the industry-wide level, particularly in industries that utilize many common technologies and component supply sources. Both agencies believe there are indeed many factors that cause costs to decrease over time. Research in the costs of manufacturing has consistently shown that, as manufacturers gain experience in production, they are able to apply innovations to simplify machining and assembly operations, use lower cost materials, and reduce the number or complexity of component parts. All of these factors allow manufacturers to lower the per-unit cost of production (*i.e.*, the manufacturing learning curve).⁸⁰⁰

In this analysis, the agencies are using the same approach to learning as done in the proposal and in past GHG/CAFE/fuel consumption rules. In short, learning effects result in rapid cost reductions in the early years following introduction of a new technology. The agencies have estimated those cost reductions as resulting in 20 percent lower costs for every doubling of production volume. As production volumes increase, learning rates continue at the same pace but flatten asymptotically due to the nature of the persistent doubling of production

required to realize that cost reduction. As such, the cost reductions flatten out as production volumes continue to increase. Consistent with the Phase 1 rule, we refer to these two distinct portions of the “learning cost reduction curve” or “learning curve” as the steeper and flatter portions of the curve. On that steep portion of the curve, costs are estimated to decrease by 20 percent for each double of production or, by proxy, in the third and then fifth year of production following introduction. On the flat portion of the curve, costs are estimated to decrease by 3 percent per year for 5 years, then 2 percent per year for 5 years, then 1 percent per year for 5 years. Also consistent with the Phase 1 rule, the majority of the technologies we expect will be adopted are considered to be on the flat portion of the learning curve meaning that the 20 percent cost reductions are rarely applied. The agencies requested and received comments on our approach to estimating learning effects, specifically with respect to cost reductions applied to waste heat recovery and APUs. Commenters suggested that, since waste heat recovery is not in production, the agencies should not have applied learning effect to that technology. They also argued that, since APUs have been around for years, applying any cost reduction effects to their costs is “questionable.” The agencies disagree with both of these comments. Whether production-related learning-by-doing cost reductions or from other factors, we are aware of dramatic changes to waste heat recovery systems that clearly make that technology less costly. We describe these changes in more detail in Chapter 2 of the RIA. Also, to suggest that APUs cannot undergo any cost reductions from learning does not seem reasonable. The agencies have placed that technology on the flat portion of the learning curve since it is well established. As a result, the estimated learning effects are not large in scale, but to suggest that an APU will cost the same in the 2020s as it does today, in constant dollar terms, is not reasonable. Further, the commenter provided no supporting data or information to support this claim.

We provide more details on the concept of learning-by-doing and the learning effects applied in this analysis in Chapter 2.11 of the RIA.

(d) Technology Adoption Rates and Developing Package Costs

Determining the stringency of these standards involves a balancing of relevant factors—chiefly technology feasibility and effectiveness, costs, and lead time. For vocational vehicles,

tractors and trailers, the agencies have projected a technology path to achieve these standards reflecting an application rate of those technologies the agencies consider to be available at reasonable cost in the lead times provided. The agencies do not expect (and do not require) each of the technologies for which costs have been developed to be employed by all trucks and trailers across the board.⁸⁰¹ Further, many of today’s vehicles are already equipped with some of the technologies and/or are expected to adopt them by MY 2018 to comply with the HD Phase 1 standards. Estimated adoption rates in both the reference and control cases are necessary for each vehicle/trailer category. The adoption rates for most technologies are zero in the reference case; however, for some technologies—notably aero and tire technologies—the adoption rate is not zero in the reference case. These reference and control case adoption rates are then applied to the technology costs with the result being a package cost for each vehicle/trailer category. Technology adoption rates were presented in Sections II through V for engines, tractors, vocational vehicles and trailers. Individual technology costs are presented in Chapter 2.11 of the final RIA.

For HD pickups and vans, the CAFE model determines the technology adoption rates that are estimated to most cost effectively meet the standards. Similar to vocational vehicles, tractors and trailers, package costs are rarely if ever a simple sum of all the technology costs since each technology will be expected to be adopted at different rates. The methods for estimating technology adoption rates and resultant costs per vehicle (and other impacts) for HD pickups and vans are discussed above in Section VI. Individual technology costs are presented in Chapter 2.11 of the final RIA.

We provide details of expected technology adoption rates for each of the regulatory subcategories in Chapter 2 of the RIA. We present package costs both in Sections III through VI of this Preamble and in more detail in Chapter 2 of the RIA.

(e) Conversion of Technology Costs to 2013 U.S. Dollars

As noted above in Section IX.B.1, the agencies are using technology costs from many different sources. These sources, having been published in different years, present costs in different year dollars (*i.e.*, 2009 dollars or 2010

⁸⁰⁰ See “Learning Curves in Manufacturing,” L. Argote and D. Epple, Science, Volume 247; “Toward Cost Buy down Via Learning-by-Doing for Environmental Energy Technologies, R. Williams, Princeton University, Workshop on Learning-by-Doing in Energy Technologies, June 2003; “Industry Learning Environmental and the Heterogeneity of Firm Performance, N. Balasubramanian and M. Lieberman, UCLA Anderson School of Management, December 2006, Discussion Papers, Center for Economic Studies, Washington DC.

⁸⁰¹ The one exception are the design standards for non-aero box vans and non-box trailers, which do mandate use of certain tire-related technologies.

dollars). For this analysis, the agencies sought to have all costs in terms of 2013 dollars to be consistent with the dollars

used by AEO in its 2015 Annual Energy Outlook.⁸⁰² The agencies have used the GDP Implicit Price Deflator for Gross

Domestic Product as the converter, with the actual factors used as shown in Table IX–1.⁸⁰³

TABLE IX–1—IMPLICIT PRICE DEFLATORS AND CONVERSION FACTORS FOR CONVERSION TO 2013\$

	2006	2007	2008	2009	2010	2011	2012	2013
Price index for GDP	94.814	97.337	99.246	100	101.221	103.311	105.214	106.929
Factor applied for 2012\$	1.128	1.099	1.077	1.069	1.056	1.035	1.016	1.000

(2) Compliance Program Costs

The agencies have also estimated additional and/or new compliance costs associated with these standards. Normally, compliance program costs will be considered part of the indirect costs and, therefore, will be accounted for via the markup applied to direct manufacturing costs. However, since the agencies are proposing new compliance elements that were not present during development of the indirect cost markups used in this analysis, additional compliance program costs are being accounted for via a separate “line-item.” New research and development costs (see below) are being handled in the same way.

The new compliance program elements included in this rule are new powertrain testing within the vocational vehicle program, and an all-new compliance program (since none has existed to date) for the trailer program. The remaining compliance provisions are identical to those in Phase 1, and the estimated costs therefore are derived using the same methodology used to estimate compliance costs in the Phase 1 rule. Compliance program costs cover costs associated with any necessary compliance testing and reporting to the agencies. The details behind the estimated compliance program costs are provided in Chapter 7 of the RIA.

The agencies requested and received comments on our compliance cost estimates. Some commenters were concerned that we had significantly underestimated costs. In response, we have adjusted our compliance costs

estimates, including those for testing and reporting, and have increased our annual compliance costs from roughly \$6 million per year to nearly \$11 million per year. This excludes the estimated \$16 million in 2020 to build and/or upgrade facilities to conduct testing. We discuss our updated estimates in more detail in Chapter 7 of the RIA.

(3) Research and Development Costs

Much like the compliance program costs described above, we have estimated additional HDD engine, vocational vehicle and tractor R&D associated with these standards that is not accounted for via the indirect cost markups used for these segments. Much like the Phase 1 rule, EPA is estimating these additional R&D costs will occur over a 4-year timeframe as these standards come into force and industry works on means to comply. After that period, the additional R&D costs go to \$0 as R&D expenditures return to their normal levels and R&D costs are accounted for via the ICMs—and the RPEs behind them—used for these segments. The details behind the estimated R&D costs are provided in Chapter 7 of the RIA.

The agencies requested and received comments on our R&D estimates. One commenter suggested that our estimate of \$960 million over four years, for hundreds of types of disparate vehicles was unrealistic given the \$80 million of R&D spent on the Super Truck program over 5 years. Unfortunately, no better estimate was provided by commenters. We have increased our estimated R&D,

relative to that estimated in the proposal, by roughly \$14 million per year for 4 years resulting in a total additional R&D estimate of over \$1 billion. Importantly, as noted, this R&D spending is an additional expenditure above and beyond that estimated as part of the indirect cost markups which include in them an estimate of roughly 4 percent of revenues spent on R&D. Another way of stating this is that roughly 4 percent of our technology costs are actually estimated as R&D-related costs. Given our annual technology costs of \$2 billion to \$5 billion per year from 2021 through 2027, or over \$24 billion over those 7 years, we are estimating another \$1 billion in R&D via our indirect cost markups (4 percent of \$24 billion). In other words, we are really estimating roughly \$2 billion in R&D spending during the calendar years 2021 through 2027.

(4) Summary of Costs of the Vehicle Programs

The agencies have estimated the costs of the vehicle standards on an annual basis for the years 2018 through 2050, and have also estimated costs for the full model year lifetimes of MY 2018 through MY 2029 vehicles. Table IX–2 shows the annual costs of these standards along with net present values using both 3 percent and 7 percent discount rates. Table IX–3 shows the discounted model year lifetime costs of these standards at both 3 percent and 7 percent discount rates along with sums across applicable model years.

Note:

^a For an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

New technology costs begin in MY 2018 as trailers begin to add new technology. Compliance costs begin with the new standards with capital cost expenditure in that year for building and upgrading test facilities to conduct the powertrain testing in the vocational program. Research and development costs begin in 2021 and last for 4 years as engine, tractor and vocational vehicle manufacturers conduct research and development testing to integrate new technologies into their engines and vehicles.

C. Changes in Fuel Consumption and Expenditures

(1) Changes in Fuel Consumption

The new GHG and fuel consumption standards will result in significant improvements in the fuel efficiency of affected vehicles, and drivers of those vehicles will see corresponding savings associated with reduced fuel expenditures. The agencies have estimated the impacts on fuel consumption for these standards. Details behind how these changes in fuel consumption were calculated are presented in Section VII of this Preamble and in Chapter 5 of the RIA. The total number of miles that vehicles are driven each year is different under

the regulatory alternatives than in the reference case due to the “rebound effect” (discussed below in Section IX.E), so the changes in fuel consumption associated with each alternative are not strictly proportional to differences in the fuel economy levels they require.

The expected annual impacts on fuel consumption are shown in Table IX-4. Table IX-5 shows the MY lifetime changes in fuel consumption. The gallons shown in these tables as reductions in fuel consumption reflect reductions due to these standards and include any increased consumption resulting from the rebound effect (discussed below in Section IX.E).

TABLE IX-4—ANNUAL FUEL CONSUMPTION REDUCTIONS DUE TO THE FINAL PROGRAM USING METHOD B AND RELATIVE TO THE FLAT BASELINE

[Millions of gallons]^a

Calendar year	Retail gasoline			Diesel		
	Reference case	Fuel consumption reduction	% Reduction	Reference case	Fuel consumption reduction	% Reduction

Note:

^aFor an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

(2) Fuel Savings

We have also estimated the changes in fuel expenditures, or the fuel savings, using fuel prices estimated in the Energy and Information Administration's 2015 Annual Energy Outlook.⁸⁰⁴ As the AEO fuel price projections go through 2040 and not beyond, fuel prices beyond 2040 were set equal to the 2040 values. These

estimates do not account for the significant uncertainty in future fuel prices; the monetized fuel savings will be understated if actual fuel prices are higher (or overstated if fuel prices are lower) than estimated. The Annual Energy Outlook (AEO) is a standard reference used by NHTSA and EPA and many other government agencies to estimate the projected price of fuel. This has been done using both the pre-tax and post-tax fuel prices. Since the post-tax fuel prices are the prices paid at fuel pumps, the fuel savings calculated using

these prices represent the changes fuel purchasers will see. The pre-tax fuel savings measure the value to society of the resources saved when less fuel is refined and consumed. Assuming no change in fuel tax rates, the difference between these two columns represents the reduction in fuel tax revenues that will be received by state and federal governments, or about \$204 million in 2021 and \$5.8 billion by 2050 as shown in Table IX-6 where annual changes in monetized fuel savings are shown along with net present values using 3 percent

⁸⁰⁴ U.S. Energy Information Administration, Annual Energy Outlook 2015; Report Number DOE/EIA-0383(2015), April 2015.

and 7 percent discount rates. Table IX–7 and Table IX–8 show the discounted model year lifetime fuel savings using 3 percent and 7 percent discount rates, respectively.

TABLE IX–6—ANNUAL FUEL SAVINGS AND NET PRESENT VALUES AT 3% AND 7% DISCOUNT RATES USING METHOD B FOR THE FINAL PROGRAM AND RELATIVE TO THE FLAT BASELINE

[\$Millions of 2013\$]^a

Model year	Fuel savings—retail			Fuel savings—untaxed			Change in transfer

D. Maintenance Expenditures

The agencies expect increases in maintenance costs under these standards. In the NPRM, we estimated maintenance costs associated with lower rolling resistance tires. In the final rule, we have included maintenance costs for many more systems, including waste heat recovery, APUs, transmission fluids, etc. We have estimated that these maintenance costs will be incurred throughout the vehicle lifetime at intervals consistent with typical replacement intervals. Those intervals are difficult to quantify given the variety of vehicles and operating modes within the HD industry. We detail the inputs used to estimate maintenance impacts in Chapter 7.3.3 of the RIA.

We have heard from at least one source⁸⁰⁵ that strong hybrid maintenance can be higher in some ways, including possible battery replacement, but may also be much lower for some vehicle systems like brakes and general engine wear. New for the FRM, relative to the proposal, are maintenance costs on hybrid battery systems in vocational vehicles and some reduction in oil change costs on vocational vehicles with stop-start systems since less idling should result in fewer oil changes. See RIA 2.11.7. We have also included new costs for axle fluid replacements for vocational vehicles adding high efficiency axles, and transmission fluid replacements for vehicles projected to move from manual to automated transmissions. For tractors, we have added these same axle and transmission fluid costs and for the same reasons. For tractors, we have also added maintenance costs associated with auxiliary power units and for fuel operated heaters. All of the new cost estimates and the maintenance intervals

are presented in more detail in Chapter 7.2.3 of the RIA.

Table IX-9 shows the annual increased maintenance costs of the final program along with net present values using both 3 percent and 7 percent discount rates. Table IX-10 shows the discounted model year lifetime increased maintenance costs of the final program at both 3 percent and 7 percent discount rates along with sums across applicable model years.

E. Analysis of the Rebound Effect

The “rebound effect” has been defined in a variety of different ways in the energy policy and economics literature. One common definition states that the rebound effect is the increase in demand for an energy service when the cost of the energy service is reduced due to efficiency improvements.^{806 807 808} In

⁸⁰⁶ Winebrake, J.J., Green, E.H., Comer, B., Corbett, J.J., Froman, S., 2012. *Estimating the direct rebound effect for on-road freight transportation*. Energy Policy 48, 252–259.

⁸⁰⁷ Greene, D.L., Kahn, J.R., Gibson, R.C., 1999. “Fuel economy rebound effect for U.S. household vehicles,” *The Energy Journal*, 20.

⁸⁰⁸ For a discussion of the wide range of definitions found in the literature, see Appendix D: Discrepancy in Rebound Effect Definitions, in EERA (2014), “Research to Inform Analysis of the Heavy-Duty vehicle Rebound Effect,” Excerpts of Draft Final Report of Phase 1 under EPA contract EP-C–

⁸⁰⁵ Allison Transmission’s Responses to EPA’s Hybrid Questions, November 6, 2014.

the context of heavy-duty vehicles (HDVs), this can be interpreted as an increase in HDV fuel consumption resulting from more intensive vehicle use in response to increased vehicle fuel efficiency.⁸⁰⁹ Although much of this vehicle use increase is likely to take the form of increases in the number of miles vehicles are driven, it can also take the form of increases in the loaded weight at which vehicles operate or changes in traffic and road conditions vehicles encounter as operators alter their routes and schedules in response to improved fuel efficiency. Because this more intensive use consumes fuel and generates emissions, it reduces the fuel savings and avoided emissions that would otherwise be expected to result from the increases in fuel efficiency in this rulemaking.

In our analysis and discussion below, we focus on one widely-used metric to estimate the rebound effect associated with all types of more intensive vehicle use, the increase in vehicle miles traveled (VMT) that results from improved fuel efficiency. VMT can often provide a reasonable approximation for all types of more intensive vehicle use. For simplicity, we refer to this as “the VMT rebound effect” or “the direct VMT rebound” throughout this section, although we acknowledge that it is an approximation to the rebound effect associated with all types of more intensive vehicle use. The agencies use our VMT rebound estimates to generate VMT inputs that are then entered into the EPA MOVES national emissions inventory model and the Volpe Center’s HD CAFE model. Both of these models use these inputs along with many others to generate projected emissions and fuel consumption changes resulting from each of the regulatory alternatives analyzed.

The following sections describe the factors affecting the magnitude of HDV VMT rebound; review the econometric and other evidence related to HDV VMT rebound; and summarize how we estimated the HDV rebound effect for this rulemaking.

(1) Factors Affecting the Magnitude of HDV VMT Rebound

The magnitude and timing of HDV VMT rebound are driven by the interaction of many different factors.⁸¹⁰ Fuel savings resulting from fuel efficiency standards may cause HDV operators and their customers to change their patterns of HDV use and fuel consumption in a variety of ways. As discussed in the RIA (Chapter 8), HDV VMT rebound estimates determined via other proxy elasticities vary, but in no case has there been an estimate that fully offsets the fuel saved due to efficiency improvements (*i.e.*, no rebound effect greater than or equal to 100 percent).⁸¹¹

If fuel cost savings are passed on to the HDV operators’ customers (*e.g.*, logistics businesses, manufacturers, retailers, municipalities, utilities consumers, etc.), those customers might reorganize their logistics and distribution networks over time to take advantage of lower operating costs. For example, customers might order more frequent shipments or choose products that entail longer shipping distances, while freight carriers might divert some shipments to trucks from other shipping modes such as rail, barge or air. In addition, customers might choose to reduce their number of warehouses, reduce shipment rates or make smaller but more frequent shipments, all of which could lead to an increase in HDV VMT. Ultimately, fuel cost savings could ripple through the entire economy, thus increasing demand for goods and services shipped by trucks, and therefore increase HDV VMT due to increased gross domestic product (GDP).

Conversely, if fuel efficiency standards lead to net increases in the total costs of HDV operation because fuel cost savings do not fully offset the increase in HDV purchase prices and associated depreciation costs, then the price of HDV services could rise. This is likely to spur a decrease in HDV VMT, and perhaps a shift to alternative

shipping modes. These effects could also ripple through the economy and affect GDP. Note, however, that we project fuel cost savings will offset technology costs in our analysis supporting the final standards.

It is also important to note that any increase in HDV VMT resulting from the final standards may be offset, to some extent, by a decrease in VMT by older HDVs. This may occur if lower fuel costs resulting from our standards cause multi-vehicle fleet operators to shift VMT to newer, more efficient HDVs in their fleet or cause operators with newer, more efficient HDVs to be more successful at winning contracts than operators with older HDVs.

Also, as discussed in Chapter 8.2 of the RIA, the magnitude of the rebound effect is likely to be influenced by the extent of any market failures that affect the demand for more fuel efficient HDVs, as well as by HDV operators’ responses to their perception of the tradeoff between higher upfront HDV purchase costs versus lower but uncertain future expenditures on fuel.

(2) Recent Econometric and Other Evidence Related to HDV VMT Rebound

As discussed above, HDV VMT rebound is defined as the change in HDV VMT that occurs in response to an increase in HDV fuel efficiency. We are not aware of any studies that directly estimate this elasticity for the U.S. In the proposal, we discussed a number of econometric analyses of other related elasticities that could potentially be used as a proxy for measuring HDV VMT rebound, as well as several other analyses that may provide insight into the magnitude of HDV VMT rebound.⁸¹² These studies produced a wide range of estimates for HDV VMT rebound, however, and we were unable to draw any strong conclusions about the magnitude of rebound based on this available literature.

We also discussed several challenges that researchers face in attempting to quantify the VMT rebound effect for HDVs,⁸¹³ including limited data on the HD sector and the difficulty of specifying mathematical models that reflect the complex set of factors that influence HD VMT. Given these limitations, the agencies requested comment on a number of aspects of the proposed VMT rebound analysis, including procedures for measuring the rebound effect and the studies discussed in the proposal. The agencies also committed to reviewing and considering revisions to VMT rebound estimates for

13–025. (Docket ID: EPA–HQ–OAR–2014–0827). See also Greening, L.A., Greene, D.L., Difiglio, C., 2000, “Energy efficiency and consumption—the rebound effect—a survey,” *Energy Policy*, 28, 389–401.

⁸⁰⁹ We discuss other potential rebound effects in Section E.3.b., such as the indirect and economy-wide rebound effects. Note also that there is more than one way to measure HDV energy services and vehicle use. The agencies’ analyses use VMT as a measure (as discussed below); other potential measures include ton-miles, cube-miles, and fuel consumption.

⁸¹⁰ These factors are discussed more fully in a report to EPA from EERA, which illustrates in a series of diagrams the complex system of decisions and decision-makers that could influence the magnitude and timing of the rebound effect. See Sections 2.2.2, 2.2.3, 2.2.4, and 2.3 in EERA (2014), “Research to Inform Analysis of the Heavy-Duty Vehicle Rebound Effect,” Excerpts of Draft Final Report of Phase 1 under EPA contract EP–C–13–025 (EPA–HQ–OAR–2014–0827–0514).

⁸¹¹ Elasticity is the measurement of how responsive an economic variable is to a change in another. For example: *Price elasticity of demand* is a measure used in economics to show the responsiveness, or elasticity, of the quantity demanded of a good or service to a change in its price. More precisely, it gives the percentage change in quantity demanded in response to a one percent change in price.

⁸¹² See 80 FR 40448–40452.

⁸¹³ See 80 FR 40448–40452.

the final rule based on submissions from public commenters and new research on the rebound effect.

This section reviews new econometric analyses that have been produced since the release of the proposal. All of these analyses study the change in HDV use (measured in VMT, ton-mile, or fuel consumption) in response to changes in fuel price (\$/gallon) or fuel cost (\$/mile or \$/ton-mile). The studies presented below attempt to estimate these elasticities in the HDV sector using varying approaches and data sources.

Concurrent with the development of the proposal for this rule, EPA contracted with Energy and Environmental Research Associates (EERA) to analyze the HDV rebound effect for regulatory assessment purposes. Excerpts of EERA's initial report to EPA are included in the NPRM docket and contain detailed qualitative discussions of the rebound effect as well as data sources that could be used in quantitative analysis.⁸¹⁴ EERA also conducted follow-on quantitative analyses focused on estimating the impact of fuel prices on VMT and fuel consumption. We included a Working Paper in the NPRM docket that described much of this work.⁸¹⁵ Note that EERA's Working Paper was not available at the time the agencies conducted the analysis of the rebound effect for the proposal, but that the agencies agreed to consider this work and any other work in the analysis supporting the final rule.

At the time of publication of the NPRM, Winebrake et al. (2015) published two papers in Transportation Research Part D: Transport and Environment based on the EERA work mentioned above.⁸¹⁶ These two papers have been filed in each agency's docket and received public review and comment. In the first paper, the fuel price elasticities of VMT and fuel consumption for combination trucks are estimated with regression models. The combination trucks paper uses annual data for the period 1970–2012. VMT and fuel consumption are used as the

dependent variables. The control variables include: A macroeconomic variable (e.g., gross domestic product (GDP)), imports/exports, and fuel price, among other variables. In the second paper, the fuel price elasticity of VMT for single unit vehicles is estimated by using annual data for the period 1980–2012. The single unit vehicle paper uses similar control variables but includes additional variables related to lane miles and housing construction. VMT is the only dependent variable modeled in the single unit vehicle paper (i.e., fuel consumption is not modeled).

The results in Winebrake et al. are that the null hypothesis—which states that the fuel price elasticity of VMT and the fuel price elasticity of fuel consumption are zero—cannot be rejected with statistical confidence. The papers hypothesize that low elasticities may be due to a range of possibilities including: (1) The common use of fuel surcharges; (2) adjustments in other operational costs such as labor; (3) possible principal-agent problems affecting driver behavior; and (4) the nature of freight transportation as an input to a larger supply chain system that is driven by other factors. These two papers suggest that previous regulatory analysis that uses a five percent rebound effect for combination trucks and a 15 percent rebound effect for single unit trucks may be overestimating the direct VMT rebound effect.

To the best of our knowledge, the Winebrake et al. paper represents the first peer-reviewed work in the last two decades, after Gately (1990),⁸¹⁷ that attempts to estimate quantitatively the impact of a change in fuel costs on HDV VMT in the U.S. context. A subsequent paper by Wadud, discussed in more detail below, states that there is “only one creditable study” on “the responses of different [heavy duty] vehicle sectors to fuel price or income changes,” specifically the Winebrake et al. combination truck work.

However, there is also other recent work that has not been peer reviewed, or that studies HD VMT rebound in other countries, that bears mention. Resources for the Future (RFF) filed a comment on the proposal with a Working Paper by Leard et al. (2015) to address HDV rebound effects.^{818 819}

⁸¹⁷ Gately, D., 1990. *The U.S. demand for highway travel and motor fuel*. Energy J. 11, 59–74.

⁸¹⁸ Resources for the Future (RFF) comment, EPA-HQ-OAR–2014–0827–1200.

⁸¹⁹ Leard, B., et al., *Fuel Costs, Economic Activity, and the Rebound Effect for Heavy-Duty Trucks*. September 2015, Resources for the Future: RF DP 15–43, Washington, DC. EPA-HQ-OAR–2014–0827–1200–A1.

Leard et al.'s paper uses detailed truck-level micro-data from the Vehicle Inventory and Use Survey (VIUS) for six survey years (specifically, 1977, 1982, 1987, 1992, 1997, and 2002). The “rebound effect” in this paper is defined to be a combination of a “VMT elasticity with respect to fuel costs per mile” (\$/mile); and a “truck count elasticity with respect to fuel costs per mile.” Fuel costs per mile are defined as fuel price (\$/gal) divided by efficiency (mpg). Because the agencies do not estimate the directional impact of this rulemaking on vehicle sales, the portion of Leard et al.'s estimates associated with VMT rebound with respect to fuel costs per mile are the most useful point of comparison to the estimates in the proposal for this rulemaking.

Leard et al. report a VMT rebound effect result of 18.5 percent with respect to fuel costs per mile for combination trucks.⁸²⁰ This finding suggests that previous estimates of combination truck rebound effects used in the proposed rule, a five percent rebound effect, may be underestimating the true rebound effect. Leard et al. also report a VMT rebound effect with respect to fuel costs per mile of 12.2 percent for single unit trucks.⁸²¹ This finding (like the findings of the Winebrake paper) suggests that the previous use of a 15 percent rebound effect for single unit vehicles in the proposed rule may be overestimating the true rebound effect. As noted, VIUS was discontinued in 2002, so the most recent data in this study is 2002, which is fourteen years old. The Leard et al. Working Paper has not yet been peer reviewed or published.

Recently, Wadud (2016) has estimated price elasticities of diesel demand in the U.K.⁸²² The paper aims to model diesel demand elasticities for different freight duty vehicle types in the U.K. Wadud uses a similar model specification as Winebrake et al. in the regression analysis. Wadud finds that diesel consumption in freight vehicles overall is quite inelastic. Diesel demand from articulated trucks and large goods vehicles (similar to combination trucks in the U.S.) does not respond to changes

⁸²⁰ Leard et al. report a total VMT rebound effect result of 29.7 percent for combination trucks, which is a sum of separate estimates associated with both VMT elasticity and truck count elasticity with respect to fuel costs per mile.

⁸²¹ For vocational trucks, Leard et al. report an overall 9.3 percent rebound value, which is a sum of separate estimates associated with both VMT elasticity and truck count elasticity with respect to fuel costs per mile.

in diesel prices. Demand in rigid trucks (similar to single unit trucks in the U.S.) responds to fuel price changes with a 15 percent elasticity. Wadud's work presents empirical results in the U.K., which might not be necessarily be appropriate to apply to the U.S.

(3) How the Agencies Estimated the HDV Rebound Effect for the Final Rule

(a) Values Used in the Phase 2 NPRM Analysis

At the time the agencies conducted their analysis of the proposed Phase 2 HD fuel efficiency and GHG emissions standards, the agencies determined that the evidence did not lend itself to any changes in the values used to estimate the VMT rebound effect in the HD Phase 1 rulemaking. The agencies used the rebound effects estimate of 15 percent for vocational vehicles five percent for combination tractors, and 10 percent for HD pickup trucks and vans from the HD Phase 1 rulemaking.

(b) How the Agencies Analyzed VMT Rebound in This Final Rulemaking

The emergence of new information as well as public comment are cause for updating the quantitative values used to estimate the VMT rebound effect from those estimated by the analysis conducted for the HD Phase 1 rulemaking. For vocational trucks, the Winebrake et al. study found no responsiveness of truck travel to diesel fuel prices, suggesting a VMT rebound of essentially zero. Leard et al. suggested a VMT rebound effect for vocational trucks of roughly 12 percent. For combination trucks, the Winebrake et al. study found a rebound effect of essentially zero percent. The Leard et al. study found a VMT elasticity rebound effect of roughly 18 percent for combination trucks. In addition to the RFF comments to which Leard et al. was included, EPA and NHTSA received ten other comments on HDV rebound during the comment period for the proposal, six of which were substantive. One of these commenters suggested that the agencies' rebound numbers "appear reasonable." The five others commented that the rebound estimates for both combination and vocational vehicles used in the proposal were overestimated, and suggested using the Winebrake et al. estimates.

In revising the HD VMT rebound estimates, we give somewhat greater consideration to the findings of Winebrake et al. because it is peer-reviewed and published, whereas Leard et al. is a Working Paper. Based on this consideration and on the comments that we received in response to the proposal,

the agencies have chosen to revise the VMT rebound estimate for vocational trucks down to five percent, and have elected to maintain the use of the five percent rebound effect for tractors. We note that while the Winebrake et al. work supports rebound estimates of zero percent for vocational vehicles and tractors, using a five percent value is conservative and leaves some consideration of uncertainty, as well as some consideration of the (un-peer reviewed and unpublished) findings of the Leard et al. study. The five percent value is in range of the two U.S. studies and generally addresses the issues raised by the commenters. We did not receive new data or comments on our estimated VMT rebound effect for heavy-duty pick-up trucks and vans. Therefore, we have elected to use the 10 percent value used for the proposal.

It should be noted that the rebound estimates we have selected for our analysis represent the VMT impact from the final standards with respect to changes in the fuel cost per mile driven. As described in the RIA (Chapter 8), the HDV rebound effect should ideally be a measure of the change in fuel consumed with respect to the change in *overall* operating costs due to a change in HDV fuel efficiency. Such a measure would incorporate all impacts from our rules, including those from incremental increases in vehicle prices that reflect costs for improving their fuel efficiency. Therefore, VMT rebound estimates with respect to fuel costs per mile must be "scaled" to apply to total operating costs, by dividing them by the fraction of total operating costs accounted for by fuel use.

In the NPRM, due to timing constraints, we used the same "overall" VMT rebound value for each of the alternatives. For the final rulemaking, we determined VMT rebound separately for each HDV category and for each alternative. The agencies made simplifying assumptions in the VMT rebound analysis for this final rulemaking, similar to the approach taken during HD Phase 1 final rules. For example, due to timing constraints, the agencies did not have the final technology package costs for each of the alternatives prior to the need to conduct the emission inventory analysis. Therefore, the agencies used the technology package costs developed for each of the NPRM alternatives. Chapter 8.3.3 in the RIA provides more details on our assessment of HDV VMT rebound. In addition, Chapter 7 of the RIA presents VMT rebound for each HDV sector that we estimated for the final program. These VMT impacts are reflected in the estimates of total fuel

savings and reductions in emissions of GHG and other air pollutants presented in Section VII and VIII of this Preamble for all categories.

For the purposes of this final rulemaking, we have not taken into account any potential fuel savings or GHG emission reductions from the rail sector due to mode shift because estimates of this effect seem too speculative at this time. Similarly, we have not taken into account any fuel savings or GHG emissions reductions from the potential shift in VMT from older HDVs to newer, more efficient HDVs because we have found no evidence of this potential effect from fuel efficiency standards. The agencies requested comment on these assumptions in the NPRM, but did not receive any.

Note that while we focus on the VMT rebound effect in our analysis of these final rules, there are at least two other types of rebound effects discussed in the energy policy and economics literature. In addition to VMT rebound effects, there are "indirect" rebound effects, which refers to the purchase of other goods or services (that consume energy) with the costs savings from energy efficiency improvements; and "economy-wide" rebound effects, which refers to the increased demand for energy throughout the economy in response to the reduced market price of energy that happens as a result of energy efficiency improvements. One commenter pointed out that consumers may use their savings from lower fuel costs as a result of the direct rebound effect to buy more goods and services, which indirectly increases the use of energy (*i.e.*, the indirect rebound effect).⁸²³ The commenter states that the indirect rebound effect represents a positive economic result for consumers, since consumer welfare increases, although it could result in increased energy use and GHG emissions. We agree with the commenter's observation that, to the extent that indirect rebound does occur, it could have both positive and negative impacts.

Another commenter suggested that the indirect or economy-wide rebound effect could be large enough so as to fully offset the fuel savings and GHG emissions benefits of the rule.⁸²⁴ The commenter provides multiple estimates of the potential size of the indirect rebound effect. However, the unpublished methodology used to perform these estimates has not undergone peer review and, as explained in the response to comment

⁸²³ EPA-HQ-OAR-2014-0827-1336.

⁸²⁴ EPA-HQ-OAR-2014-0827-1467.

document, the agencies find it to be dubious. Further, as discussed in detail in the proposal rule and our response to comment document, there are a number of other important questions not addressed by the commenter that must be examined before we can have enough confidence in these kinds of estimates to include them in our economic analysis.

As discussed in this rule, all of the fuel costs savings will not necessarily be passed through to the consumer in terms of cheaper goods and services. First, there may be market barriers that impede trucking companies from passing along the fuel cost savings from the rule in the form of lower rates. Second, there are upfront vehicle costs (and potentially transaction or transition costs associated with the adoption of new technologies) that would partially offset some of the fuel cost savings from our rule, thereby limiting the magnitude of the impact on prices of final goods and services. Also, it is not clear how the fuel savings from the rule would be utilized by trucking firms. For example, trucking firms may reinvest fuel savings in their own company; retain fuel savings as profits; pass fuel savings onto customers or others; or increase driver pay. Finally, it is not clear how the different pathways that fuel savings would be utilized would affect greenhouse gas emissions.

Research on indirect and economy-wide rebound effects is scant, and we have not identified any peer-reviewed research that attempts to quantify indirect or economy-wide rebound effects for HDVs. In particular, the agencies are not aware of any peer-reviewed approach which indicates that the magnitude of indirect or economy-wide rebound effects, if any, would be significant for this final rule.⁸²⁵ Therefore, we rely on the analysis of vehicle miles traveled to estimate the rebound effect in this rule, as we did for the HD Phase 1 rule, where we attempted to quantify only rebound

effects from our rule that impact HDV VMT.

In order to test the effect of alternative assumptions about the rebound effect, NHTSA examined the sensitivity of its estimates of benefits and costs of the proposed Phase 2 program for HD pickups and vans to alternative assumptions about the rebound effect. While the main analysis for pickups and vans assumes a 10 percent rebound effect, the sensitivity analysis estimates the benefits and costs of these standards under the assumptions of 5, 15, and 20 percent rebound effects. This sensitivity analysis can be found in Section IX.E.3 of the NPRM Preamble⁸²⁶ and shows that (a) using a 5 percent value for the rebound effect reduced benefits and costs of the proposed standards by identical amounts, leaving net benefits unaffected; and (b) rebound effects of 15 percent and 20 percent increased costs and reduced benefits compared to their values in the main analysis, thus reducing net benefits of the proposed standards. Nevertheless, the proposed and now the final program have significant net benefits and these alternative values of the rebound effect would not have affected the agencies' selection of the final program stringency, as that selection is based on NHTSA's assessment of the maximum feasible fuel efficiency standards and EPA's selection of appropriate GHG standards to address energy security and the environment.

F. Impact on Class Shifting, Fleet Turnover, and Sales

The agencies considered two additional potential indirect effects which may lead to unintended consequences of the program to improve the fuel efficiency and reduce GHG emissions from HD trucks. The next sections cover the agencies' qualitative discussions on potential class shifting and fleet turnover effects.

(1) Class Shifting

Heavy-duty vehicles are typically configured and purchased to perform a function. For example, a concrete mixer truck is purchased to transport concrete, a combination tractor is purchased to move freight with the use of a trailer, and a Class 3 pickup truck could be purchased by a landscape company to pull a trailer carrying lawnmowers. The purchaser makes decisions based on many attributes of the vehicle, including the gross vehicle weight rating of the vehicle, which in part determines the amount of freight or equipment that can be carried. If the Phase 2 standards

impact either the performance of the vehicle or the marginal cost of the vehicle relative to the other vehicle classes, then consumers may choose to purchase a different vehicle, resulting in the unintended consequence of increased fuel consumption and GHG emissions in-use.

The agencies, along with the NAS panel, found that there is little or no literature which evaluates class shifting between trucks.⁸²⁷ In addition, the agencies did not receive comments specifically raising concerns about class shifting. NHTSA and EPA qualitatively evaluated the final rules in light of potential class shifting. The agencies looked at four potential cases of shifting: From light-duty pickup trucks to heavy-duty pickup trucks; from sleeper cabs to day cabs; from combination tractors to vocational vehicles; and within vocational vehicles.

Light-duty pickup trucks, those with a GVWR of less than 8,500 lbs, are currently regulated under the existing GHG/CAFE standards for light duty vehicles. The increased stringency of the light-duty 2017–2025 MY vehicle rule has led some to speculate that vehicle consumers may choose to purchase heavy-duty pickup trucks that are currently regulated under the HD Phase 1 program if the cost of the light-duty regulation is high relative to the cost to buy the larger heavy-duty pickup trucks. Since fuel consumption and GHG emissions rise significantly with vehicle mass, a shift from light-duty trucks to heavy-duty trucks would likely lead to higher fuel consumption and GHG emissions, an untended consequence of the regulations. Given the significant price premium of a heavy-duty truck (often five to ten thousand dollars more than a light-duty pickup), we believe that such a class shift would be unlikely whether or not this program existed. These final rules would continue to diminish any incentive for such a class shift because they would narrow the GHG and fuel efficiency performance gap between light-duty and heavy-duty pickup trucks. The regulations for the HD pickup trucks, and similarly for vans, are based on similar technologies and therefore reflect a similar expected increase in cost when compared to the light-duty GHG regulation. Hence, the combination of the two regulations provides little incentive for a shift from light-duty trucks to HD trucks. To the extent that this regulation of heavy-duty pickups and vans could conceivably encourage a class shift towards lighter pickups, this unintended consequence

⁸²⁵ The same entity responsible for these comments also sought reconsideration of the Phase 1 rule on the grounds that indirect rebound effects had not been considered by the agencies and could negate all of the benefits of the standards. This assertion rested on an unsupported affidavit lacking any peer review or other indicia of objectivity. This affidavit cited only one published study. The study cited did not deal with vehicle efficiency, has methodological limitations (many of them acknowledged), and otherwise was not pertinent. EPA and NHTSA thus declined to reconsider the Phase 1 rule based on these speculative assertions. See generally 77 FR 51703–51704, August 27, 2012 and 77 FR 51502–51503, August 24, 2012. The analysis in this entity's comments on this rulemaking rests largely on that same unsupported affidavit.

⁸²⁶ 80 FR 40137.

⁸²⁷ See 2010 NAS Report, page 152.

would in fact be expected to lead to lower fuel consumption and GHG emissions as the smaller light-duty pickups have significantly better fuel economy ratings than heavy-duty pickup trucks.

The projected cost increases for this action differ between Class 8 day cabs and Class 8 sleeper cabs, reflecting our conservative assumption for purposes of this analysis on shifting that compliance with these standards would lead truck consumers to specify sleeper cabs equipped with APUs or alternatives to APU while day cab consumers would not. Since Class 8 day cab and sleeper cab trucks perform essentially the same function when hauling a trailer, this raises the possibility that the additional cost for an APU or alternatives to APU equipped sleeper cab could lead to a shift from sleeper cab to day cab trucks. We do not believe that such an intended consequence would occur for the following reasons. The addition of a sleeper berth to a tractor cab is not a consumer-selectable attribute in quite the same way as other vehicle features. The sleeper cab provides a utility that long-distance trucking fleets need to conduct their operations—an on-board sleeping berth that lets a driver comply with federally-mandated rest periods, as required by the Department of Transportation Federal Motor Carrier Safety Administration's hours-of-service regulations. The cost of sleeper trucks is already higher than the cost of day cabs, yet the fleets that need this utility purchase them.⁸²⁸ A day cab simply cannot provide this utility with a single driver. The need for this utility would not be changed even if the additional costs to reduce greenhouse gas emissions from sleeper cabs exceed those for reducing greenhouse gas emissions from day cabs.⁸²⁹

A trucking fleet could instead decide to put its drivers in hotels in lieu of using sleeper berths, and switch to day cabs. However, this is unlikely to occur in any great number, since the added cost for the hotel stays would far overwhelm differences in the marginal cost between day and sleeper cabs. Even if some fleets do opt to buy hotel rooms and switch to day cabs, they would be highly unlikely to purchase a day cab that was aerodynamically worse than

the sleeper cab they replaced, since the need for features optimized for long-distance hauling would not have changed. So in practice, there would likely be little difference to the environment for any switching that might occur. Further, while our projected costs in the NPRM assumed the purchase of an APU for compliance for nearly all sleeper cabs, the updated analysis reflects additional flexibility in the final rules that would allow manufacturers to use several other alternatives to APUs that would be much less expensive. Thus, even though we are now projecting that APU costs will be somewhat higher than what we projected for the NPRM, manufacturers and consumers will not be required to use them. In fact, this regulatory structure would allow compliance using a near zero cost software utility that eliminates tractor idling after five minutes. Using this compliance approach, the cost difference between a Class 8 sleeper cab and day cab due to these regulations is small. We are proposing this alternative compliance approach reflecting that some sleeper cabs are used in team driving situations where one driver sleeps while the other drives. In that situation, an APU is unnecessary since the tractor is continually being driven when occupied. When it is parked, it would automatically eliminate any additional idling through the shutdown software. If trucking businesses choose this option, then costs based on purchase of APUs may overestimate the costs of this program to this sector.

Class shifting from combination tractors to vocational vehicles may occur if a customer deems the additional marginal cost of tractors due to the regulation to be greater than the utility provided by the tractor. The agencies initially considered this issue when deciding whether to include Class 7 tractors with the Class 8 tractors or regulate them as vocational vehicles. The agencies' evaluation of the combined vehicle weight rating of the Class 7 shows that if these vehicles were treated significantly differently from the Class 8 tractors, then they could be easily substituted for Class 8 tractors. Therefore, the agencies will continue to include both classes in the tractor category. The agencies believe that a shift from tractors to vocational vehicles would be limited because of the ability of tractors to pick up and drop off trailers at locations which cannot be done by vocational vehicles.

The agencies do not envision that the regulatory program would cause class shifting within the vocational vehicle class. As vocational vehicles include a

wide variety of vehicle types, and serve a wide range of functions, the diversity in the vocational vehicle segment can be primarily attributed to the variety of customer needs for specialized vehicle bodies and added equipment, rather than to the chassis. The new standards are projected to lead to a small increase in the incremental cost per vehicle. However, these cost increases are consistent across the board for both vocational vehicles and the engines used in the vehicle (Table V-30 at Preamble Section V.C.(2)(e)). The agencies believe that the utility gained from the additional technology package would outweigh the additional cost for vocational vehicles.⁸³⁰

In conclusion, NHTSA and EPA believe that the regulatory structure for HD vehicles and engines would not significantly change the current competitive and market factors that determine purchaser preferences. Furthermore, even if a small amount of shifting would occur, any resulting GHG impacts would likely be negligible because any vehicle class that sees an uptick in sales is also being regulated for GHG emission control and fuel efficiency. Therefore, the agencies did not include an impact of class shifting on the vehicle populations used to assess the benefits of the program.

(2) Fleet Turnover and Sales Effects

A regulation that affects the cost to purchase and/or operate trucks could affect whether a consumer decides to purchase a new truck and the timing of that purchase. The term pre-buy refers to the idea that truck purchases may occur earlier than otherwise planned to avoid the additional costs associated with a new regulatory requirement. Slower fleet turnover, or low-buys, may occur when owners opt to keep their existing truck rather than purchase a new truck due to the incremental cost of the regulation.

Several commenters raised the possibility of pre-buy for these standards. Allison Transmission, the National Automobile Dealers Association, the Owner-Operator Independent Drivers Association, and the Truck Renting and Leasing Association point toward pre-buy associated with standards from the 2000s for nitrogen oxides (NO_x) regulations as evidence of the likelihood

⁸²⁸ A baseline tractor price of a new day cab is \$89,500 versus \$113,000 for a new sleeper cab based on information gathered by ICF in the "Investigation of Costs for Strategies to Reduce Greenhouse Gas Emissions for Heavy-Duty On-Road Vehicles," July 2010. Page 3. Docket Identification Number EPA-HQ-OAR-2014-0827.

⁸²⁹ The average marginal cost difference between sleeper cabs and day cabs in the rule is roughly \$2,500.

⁸³⁰ The final rule projects the average per-vehicle costs associated with the 2027 MY standards to be generally less than five percent of the overall price of a new vehicle. The cost-effectiveness of these vocational vehicle standards in dollars per ton is similar to the cost effectiveness estimated for light-duty trucks in the 2017-2025 light duty greenhouse gas standards (Preamble section V.C.3).

of pre-buy for vehicle GHG and fuel efficiency standards. Daimler Trucks North America, the International Union, United Automobile, Aerospace, and Agricultural Implement Workers of America, and the Truck and Engine Manufacturers Association express concern about pre-buy specifically in the context of NPRM Alternative 4, due to concerns that the time frame for technology development and adoption was too short. Daimler Trucks and the Environmental Defense Fund note that Phase 1 did not appear to result in pre-buy. Volvo Group notes that the phase-in approach of Phase 1 plus the flexibilities available eased the transition to new technologies, and that gradual market acceptance of new technologies will lead to less disruption than an accelerated program. The Recreational Vehicle Industry Association expressed concern that the standards will have a negative effect on recreational vehicle sales.

The 2010 NAS HD Report discussed the topics associated with medium- and heavy-duty vehicle fleet turnover. NAS noted that there is some empirical evidence of pre-buy behavior in response to the 2004 and 2007 heavy-duty engine emission standards, with larger impacts occurring in response to higher costs.⁸³¹ However, those regulations increased upfront costs to firms without any offsetting future cost savings from reduced fuel purchases. In summary, NAS stated that:

... during periods of stable or growing demand in the freight sector, pre-buy behavior may have significant impact on purchase patterns, especially for larger fleets with better access to capital and financing. Under these same conditions, smaller operators may simply elect to keep their current equipment on the road longer, all the more likely given continued improvements in diesel engine durability over time. On the other hand, to the extent that fuel economy improvements can offset incremental purchase costs, these impacts will be lessened. Nevertheless, when it comes to efficiency investments, most heavy-duty fleet operators require relatively

quick payback periods, on the order of two to three years.⁸³²

The regulations are projected to return fuel savings to the vehicle owners that offset the cost of the regulation within a few years. The effects of the regulation on purchasing behavior and sales will depend on the nature of the market failures and the extent to which firms consider the projected future fuel savings in their purchasing decisions.

If trucking firms or other buyers account for the rapid payback, they are unlikely to strategically accelerate or delay their purchase plans at additional cost in capital to avoid a regulation that will lower their overall operating costs. As discussed in Section IX.A., this scenario may occur if this program reduces uncertainty about fuel-saving technologies. More reliable information about ways to reduce fuel consumption allows truck purchasers to evaluate better the benefits and costs of additional fuel savings, primarily in the original vehicle market, but possibly in the resale market as well. In addition, these standards are expected to lead manufacturers to install more fuel-saving technologies and promote their purchase; the increased availability and promotion may encourage sales.

Other market failures may leave open the possibility of some pre-buy or delayed purchasing behavior. Firms may not consider the full value of the future fuel savings for several reasons. For instance, truck purchasers may not want to invest in fuel efficiency because of uncertainty about fuel prices. Another explanation is that the resale market may not fully recognize the value of fuel savings, due to lack of trust of new technologies or changes in the uses of the vehicles. Lack of coordination (also called split incentives—see Section IX.A) between truck purchasers (who may emphasize the up-front costs of the trucks) and truck operators, who like the fuel savings, can also lead to pre-buy or delayed purchasing behavior. If these market failures prevent firms from fully internalizing fuel savings when deciding on vehicle purchases, then pre-buy and delayed purchase could occur and could result in a slight decrease in the GHG benefits of the regulation.

Thus, whether pre-buy or delayed purchase is likely to play a significant role in the truck market depends on the specific behaviors of purchasers in that market. Without additional information about which scenario is more likely to be prevalent, the agencies are not

projecting a change in fleet turnover characteristics due to this regulation.

Industry purchasing in relation to the advent of the Phase 1 standards offers at least some insight into the impacts of these standards. The Environmental Defense Fund observes that MY 2014 heavy-duty trucks had the highest sales since 2005. Any trends in sales are likely to be affected by macroeconomic conditions, which have been recovering since 2009–2010. The standards may have affected sales, but the size of that effect is likely to be swamped by the effects of the economic recovery. It is unlikely to be possible to separate the effects of the existing standards from other confounding factors.

G. Monetized GHG Impacts

(1) Monetized CO₂ Impacts—The Social Cost of Carbon (SC-CO₂)

We estimate the global social benefits of CO₂ emission reductions expected from the heavy-duty GHG and fuel efficiency standards using the social cost of carbon (SC-CO₂) estimates presented in the *Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866* (May 2013, Revised July 2015) (“current SC-CO₂ TSD”).⁸³³ (The SC-CO₂ estimates are presented in Table IX–11). We refer to these estimates, which were developed by the U.S. government, as “SC-CO₂ estimates.” The SC-CO₂ is a metric that estimates the monetary value of impacts associated with marginal changes in CO₂ emissions in a given year. It includes a wide range of anticipated climate impacts, such as net changes in agricultural productivity and human health, property damage from increased flood risk, and changes in energy system costs, such as reduced costs for heating and increased costs for air conditioning. It is typically used to assess the avoided damages as a result of regulatory actions (*i.e.*, benefits of rulemakings that lead to an incremental reduction in cumulative global CO₂ emissions).

The SC-CO₂ estimates used in this analysis were developed over many

⁸³¹ Committee to Assess Fuel Economy Technologies for Medium- and Heavy-Duty Vehicles; National Research Council; Transportation Research Board (2010). “Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles,” (hereafter, “NAS Report”). Washington, DC, the National Academies Press. Available electronically from the National Academies Press Web site at http://www.nap.edu/catalog.php?record_id=12845, pp. 150–151, Docket EPA-HQ-OAR-2014-0827-0276.

⁸³² See NAS Report, Note 831, page 151, Docket EPA-HQ-OAR-2014-0827-0276.

⁸³³ *Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866* (May 2013, Revised July 2015), Interagency Working Group on Social Cost of Carbon, with participation by Council of Economic Advisers, Council on Environmental Quality, Department of Agriculture, Department of Commerce, Department of Energy, Department of Transportation, Environmental Protection Agency, National Economic Council, Office of Energy and Climate Change, Office of Management and Budget, Office of Science and Technology Policy, and Department of Treasury. Available at: <https://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-td-final-july-2015.pdf>.

years, using the best science available, and with input from the public. Specifically, an interagency working group (IWG) that included EPA, DOT, and other executive branch agencies and offices used three integrated assessment models (IAMs) to develop the SC-CO₂ estimates and recommended four global values for use in regulatory analyses. The SC-CO₂ estimates were first released in February 2010 and updated in 2013 using new versions of each IAM. The 2013 update did not revisit the 2010 modeling decisions (e.g., with regard to the discount rate, reference case socioeconomic and emission scenarios or equilibrium climate sensitivity). Rather, improvements in the way damages are modeled are confined to those that have been incorporated into the latest versions of the models by the developers themselves and used for analyses in peer-reviewed publications. The 2010 SC-CO₂ Technical Support Document (2010 SC-CO₂ TSD) provides a complete discussion of the methods used to develop these estimates and the current SC-CO₂ TSD presents and discusses the update (including recent minor technical corrections to the estimates).⁸³⁴

The 2010 SC-CO₂ TSD noted a number of limitations to the SC-CO₂ analysis, including the incomplete way in which the IAMs capture catastrophic and non-catastrophic impacts, their incomplete treatment of adaptation and technological change, uncertainty in the extrapolation of damages to high temperatures, and assumptions regarding risk aversion. Currently IAMs do not assign value to all of the important physical, ecological, and economic impacts of climate change recognized in the climate change literature due to a lack of precise information on the nature of damages and because the science incorporated into these models understandably lags behind the most recent research. Nonetheless, these estimates and the

discussion of their limitations represent the best available information about the social benefits of CO₂ reductions to inform benefit-cost analysis; see RIA of this rule and the SC-CO₂ TSDs for additional details. The new versions of the models used to estimate the values presented below offer some improvements in these areas, although further work is warranted.

Accordingly, EPA and other agencies continue to engage in research on modeling and valuation of climate impacts with the goal to improve these estimates. The EPA and other federal agencies also continue to consider feedback on the SC-CO₂ estimates from stakeholders through a range of channels, including public comments on Agency rulemakings that use the SC-CO₂ in supporting analyses and through regular interactions with stakeholders and research analysts implementing the SC-CO₂ methodology used by the IWG. The SC-CO₂ comments received on this rulemaking covered the technical details of the modeling conducted to develop the SC-CO₂ estimates and some also provided constructive recommendations for potential opportunities to improve the SC-CO₂ estimates in future updates. EPA has carefully considered all of these comments and continues to conclude that the current estimates represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental CO₂ emissions changes into regulatory analysis. Therefore, EPA has presented the current SC-CO₂ estimates in this rulemaking. See Section 11.8 of the RTC document for a summary of and response to the SC-CO₂ comments submitted to this rulemaking. In addition, OMB sought public comment on the approach used to develop the SC-CO₂ estimates through a separate comment period and published a response to those comments in 2015.⁸³⁵

After careful evaluation of the full range of comments submitted to OMB, the IWG continues to recommend the use of the SC-CO₂ estimates in regulatory impact analysis. With the July 2015 release of the response to comments, the IWG announced plans to obtain expert independent advice from the National Academies of Sciences, Engineering and Medicine to ensure that the SC-CO₂ estimates continue to reflect the best available scientific and economic information on climate change. The Academies then convened a committee, "Assessing Approaches to

Updating the Social Cost of Carbon," (Committee) which is reviewing the state of the science on estimating the SC-CO₂, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. EPA will evaluate its approach based upon any feedback received from the Academies' panel.

To date, the Committee has released an interim report, which recommended against doing a near term update of the SC-CO₂ estimates. For future revisions, the Committee recommended the IWG move efforts towards a broader update of the climate system module consistent with the most recent, best available science, and also offered recommendations for how to enhance the discussion and presentation of uncertainty in the SC-CO₂ estimates. Specifically, the Committee recommended that "the IWG provide guidance in their technical support documents about how [SC-CO₂] uncertainty should be represented and discussed in individual regulatory impact analyses that use the [SC-CO₂]" and that the technical support document for each update of the estimates present a section discussing the uncertainty in the overall approach, in the models used, and uncertainty that may not be included in the estimates. At the time of this writing, the IWG is reviewing the interim report and considering the recommendations. EPA looks forward to working with the IWG to respond to the recommendations and will continue to follow IWG guidance on SC-CO₂.

The four global SC-CO₂ estimates are as follows: \$13, \$46, \$68, and \$140 per metric ton of CO₂ emissions in the year 2020 (2013\$).⁸³⁶ The first three values are based on the average SC-CO₂ from the three IAMs, at discount rates of 5, 3, and 2.5 percent, respectively. SC-CO₂ estimates for several discount rates are included because the literature shows that the SC-CO₂ is quite sensitive to assumptions about the discount rate, and because no consensus exists on the appropriate rate to use in an intergenerational context (where costs and benefits are incurred by different generations). The fourth value is the 95th percentile of the SC-CO₂ from all three models at a 3 percent discount rate. It is included to represent lower probability but higher outcomes from

⁸³⁴ Both the 2010 SC-CO₂ TSD and the current TSD are available at: <https://www.whitehouse.gov/omb/oira/social-cost-of-carbon>. The 2010 SC-CO₂ TSD also available in the docket: Docket ID EPA-HQ-OAR-2009-0472-114577, *Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866*, Interagency Working Group on Social Cost of Carbon, with participation by the Council of Economic Advisers, Council on Environmental Quality, Department of Agriculture, Department of Commerce, Department of Energy, Department of Transportation, Environmental Protection Agency, National Economic Council, Office of Energy and Climate Change, Office of Management and Budget, Office of Science and Technology Policy, and Department of Treasury (February 2010). Also available at: <http://www.whitehouse.gov/sites/default/files/omb/inforeg/for-agencies/Social-Cost-of-Carbon-for-RIA.pdf>.

⁸³⁵ See <https://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-response-to-comments-final-july-2015.pdf>.

⁸³⁶ The current SC-CO₂ TSD presents the SC-CO₂ estimates in \$2007. These estimates were adjusted to 2013\$ using the GDP Implicit Price Deflator. Bureau of Economic Analysis, Table 1.1.9 Implicit Price Deflators for Gross Domestic Product; last revised on September 25, 2015.

climate change, which are captured further out in the tail of the SC-CO₂ distribution, and while less likely than those reflected by the average SC-CO₂ estimates, would be much more harmful to society and therefore, are relevant to policy makers. The SC-CO₂ increases over time because future emissions are expected to produce larger incremental damages as economies grow and physical and economic systems become more stressed in response to greater

climate change. The SC-CO₂ values are presented in Table IX–11.

Applying the global SC-CO₂ estimates, shown in Table, to the estimated reductions in domestic CO₂ emissions for the program, yields estimates of the dollar value of the climate related benefits for each analysis year. These estimates are then discounted back to the analysis year using the same discount rate used to estimate the SC-CO₂. For internal consistency, the annual benefits are discounted back to

net present value terms using the same discount rate as each SC-CO₂ estimate (*i.e.*, 5 percent, 3 percent, and 2.5 percent) rather than the discount rates of 3 percent and 7 percent used to derive the net present value of other streams of costs and benefits of the final rule.⁸³⁷ The SC-CO₂ benefit estimates for each calendar year are shown in Table. The SC-CO₂ benefit estimates for each model year are shown in Table IX–13.

TABLE IX–11—SOCIAL COST OF CO₂, 2012–2050^a
[in 2013\$ per Metric Ton]

Calendar year	5% Average	3% Average	2.5% Average	3%, 95th Percentile
2012	\$12	\$36	\$58	\$100
2015	12	40	62	120
2020	13	46	68	140
2025	15	51	75	150
2030	18	55	80	170
2035	20	60	86	180
2040	23	66	92	200
2045	25	70	98	220
2050	29	76	100	230

Note:

^a The SC-CO₂ values are dollar-year and emissions-year specific and have been rounded to two significant digits. Unrounded numbers from the current SC-CO₂ TSD were used to calculate the CO₂ benefits.

EPA calculated the global social benefits of CH₄ and N₂O emissions reductions expected from the final rulemaking using estimates of the social cost of methane (SC-CH₄) and the social cost of nitrous oxide (SC-N₂O). Similar to the SC-CO₂, the SC-CH₄ and SC-N₂O estimate the monetary value of impacts associated with marginal changes in CH₄ and N₂O emissions, respectively, in a given year. Each metric includes a wide range of anticipated climate impacts, such as net changes in agricultural productivity and human health, property damage from increased flood risk, and changes in energy system costs, such as reduced costs for heating and increased costs for air conditioning. The SC-CH₄ and SC-N₂O estimates applied in this analysis were developed by Marten et al. (2014) and are discussed in greater detail below. EPA is unaware of analogous estimates of HFC-134a and has therefore presented a sensitivity analysis, separate from the

main benefit cost analysis, that approximates the benefits of HFC-134a reductions based on global warming potential (GWP) gas comparison metrics (“GWP approach”). Other unquantified non-CO₂ benefits are discussed in this section as well. Additional details are provided in the RIA of these rules.

(a) Monetized CH₄ and N₂O Impacts

As discussed in the proposed rulemaking, a challenge particularly relevant to the monetization of non-CO₂ GHG impacts is that the IWG did not estimate the social costs of non-CO₂ GHG emissions at the time the SC-CO₂ estimates were developed. While there are other estimates of the social cost of non-CO₂ GHGs in the peer review literature, none of those estimates are consistent with the SC-CO₂ estimates developed by the IWG and most are likely underestimates due to changes in the underlying science subsequent to their publication.⁸³⁸

However, in the time leading up to the proposal for this rulemaking, a

paper by Marten et al. (2014) provided the first set of published SC-CH₄ and SC-N₂O estimates in the peer-reviewed literature that are consistent with the modeling assumptions the IWG used to develop the SC-CO₂ estimates.⁸³⁹ Specifically, the estimation approach of Marten et al. (2014) used the same set of three IAMs, five socioeconomic-emissions scenarios, equilibrium climate sensitivity distribution, three constant discount rates, and aggregation approach used to develop the SC-CO₂ estimates. Marten et al. also used the same rationale as the IWG to develop global estimates of the SC-CH₄ and the SC-N₂O, given that CH₄ and N₂O are global pollutants.

The resulting SC-CH₄ and SC-N₂O estimates are presented in Table IX-14. More detailed discussion of their methodology, results and a comparison to other published estimates can be found in the RIA and in Marten et al. (2014).

TABLE IX-14—SOCIAL COST OF CH₄ AND N₂O, 2012–2050^a[In 2013\$ per metric ton] [Source: Marten et al., 2014^b]

Year	SC-CH ₄				SC-N ₂ O			
	5% average	3% average	2.5% average	3% 95th percentile	5% average	3% average	2.5% average	3% 95th percentile
2012	\$440	\$1,000	\$1,400	\$2,800	\$4,000	\$14,000	\$21,000	\$36,000
2015	490	1,100	1,500	3,100	4,400	14,000	22,000	38,000
2020	590	1,300	1,800	3,500	5,200	16,000	24,000	43,000
2025	710	1,500	2,000	4,100	6,000	19,000	26,000	48,000
2030	830	1,800	2,200	4,600	6,900	21,000	30,000	54,000
2035	990	2,000	2,500	5,400	8,100	23,000	32,000	60,000

⁸³⁸ As discussed in the RIA, there is considerable variation among these published estimates in the models and input assumptions they employ. These studies differ in the emission perturbation year, employ a wide range of constant and variable

discount rate specifications, and consider a range of baseline socioeconomic and emissions scenarios that have been developed over the last 20 years. See also Reilly and Richards, 1993; Schmalensee, 1993; Fankhauser, 1994; Marten and Newbold, 2012.

TABLE IX-14—SOCIAL COST OF CH₄ AND N₂O, 2012–2050 ^a—Continued[In 2013\$ per metric ton] [Source: Marten et al., 2014 ^b]

Year	SC-CH ₄				SC-N ₂ O			
	5% average	3% average	2.5% average	3% 95th percentile	5% average	3% average	2.5% average	3% 95th percentile
2040	1,100	2,200	2,900	6,000	9,200	25,000	35,000	66,000
2045	1,300	2,500	3,100	6,700	10,000	27,000	37,000	73,000
2050	1,400	2,700	3,400	7,400	12,000	30,000	41,000	79,000

Notes:^a The values are emissions-year specific and have been rounded to two significant digits. Unrounded numbers were used to calculate the GHG benefits.^b The estimates in this table have been adjusted to reflect the minor technical corrections to the SC-CO₂ estimates described above. See the Corrigendum to Marten et al. (2014), <http://www.tandfonline.com/doi/abs/10.1080/14693062.2015.1070550>.

In addition to requesting comment on these estimates in the proposed rulemaking, EPA noted that it had initiated a peer review of the application of the Marten et al (2014) non-CO₂ social cost estimates in regulatory analysis.⁸⁴⁰ EPA also stated that, pending a favorable peer review, it planned to use the Marten et al (2014) estimates to monetize benefits of CH₄ and N₂O emission reduction in the main benefit-cost analysis of the final rule.

Since then, EPA received responses that supported use of the Marten et al. estimates. Three reviewers considered seven charge questions that covered issues such as the EPA's interpretation of the Marten et al. estimates, the consistency of the estimates with the SC-CO₂ estimates, the EPA's characterization of the limits of the GWP-approach to value non-CO₂ GHG impacts, and the appropriateness of using the Marten et al. estimates in regulatory impact analyses. The reviewers agreed with the EPA's interpretation of Marten et al.'s estimates, generally found the estimates to be consistent with the SC-CO₂ estimates, and concurred with the limitations of the GWP approach, finding directly modeled estimates to be more appropriate. While outside of the scope of the review, the reviewers briefly considered the limitations in the SC-CO₂ methodology (e.g., those discussed earlier in this section) and noted that because the SC-CO₂ and SC-CH₄ and SC-N₂O methodologies are similar, the limitations also apply to the resulting SC-CH₄ and SC-N₂O estimates.

Two of the reviewers concluded that use of the SC-CH₄ and SC-N₂O estimates developed by Marten et al. and published in the peer-reviewed literature is appropriate in RIAs, provided that the Agency discuss the limitations, similar to the discussion provided for SC-CO₂ and other economic analyses. All three reviewers encouraged continued improvements in the SC-CO₂ estimates and suggested that as those improvements are realized they should also be reflected in the SC-CH₄ and SC-N₂O estimates, with one reviewer suggesting the SC-CH₄ and SC-N₂O estimates lag this process. The EPA supports continued improvement in the SC-CO₂ estimates developed by the U.S. government and agrees that improvements in the SC-CO₂ estimates should also be reflected in the SC-CH₄ and SC-N₂O estimates. The fact that the reviewers agree that the SC-CH₄ and SC-N₂O estimates are generally consistent with the SC-CO₂ estimates that are recommended by OMB's guidance on valuing CO₂ emissions reductions, leads the EPA to conclude that use of the SC-CH₄ and SC-N₂O estimates is an analytical improvement over excluding CH₄ and N₂O emissions from the monetized portion of the benefit cost analysis.

The EPA also carefully considered the full range of public comments and associated technical issues on the Marten et al. estimates received in this rulemaking and determined that it would continue to use the estimates in the final rulemaking analysis. Based on the evaluation of the public comments

on this rulemaking, the favorable peer review of the application of Marten et al. estimates, and past comments urging EPA to value non-CO₂ GHG impacts in its rulemakings, EPA concluded that the estimates represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental CH₄ and N₂O emissions changes into regulatory analysis and has included those benefits in the main benefits analysis. Please see RTC Section 11.8 for detailed responses to the comments on non-CO₂ GHG valuation.

The application of directly modeled estimates from Marten et al. (2014) to benefit-cost analysis of a regulatory action is analogous to the use of the SC-CO₂ estimates. Specifically, the SC-CH₄ and SC-N₂O estimates in Table IX-15 are used to monetize the benefits of changes in CH₄ and N₂O emissions expected as a result of the final rulemaking. Forecast changes in CH₄ and N₂O emissions in a given year resulting from the regulatory action are multiplied by the SC-CH₄ and SC-N₂O estimate for that year, respectively. To obtain a present value estimate, the monetized stream of future non-CO₂ benefits are discounted back to the analysis year using the same discount rate used to estimate the social cost of the non-CO₂ GHG emission changes.

The CH₄ and N₂O benefits based on Marten et al. (2014) are presented for each calendar year in Table IX-15.

NPV	1,200	3,800	5,400	10,000	37	160	250	430

Notes:

^a The SC-CH₄ and SC-N₂O values are dollar-year and emissions-year specific.

^b Note that net present discounted values of reduced GHG emissions are calculated differently than other benefits. The same discount rate used to discount the value of damages from future emissions (SC-CH₄ and SC-N₂O at 5, 3, and 2.5 percent) is used to calculate net present value discounted values of SC-CH₄ and SC-N₂O for internal consistency. Refer to the 2010 SC-CO₂ TSD for more detail.

^c For an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

(b) *Sensitivity Analysis—HFC-134a Benefits Based on the GWP Approximation Approach*

While the rulemaking will result in reductions of HFC-134a, EPA is unaware of analogous estimates of the social cost of HFC-134a and has therefore used an alternative valuation approach and presented the results in this sensitivity analysis, separate from the main benefit cost analysis. Specifically, EPA has used the global warming potential (GWP) for HFC-134a to convert the emissions of this gas to CO₂ equivalents, which are then valued using the SC-CO₂ estimates. This approach, henceforth referred to as the “GWP approach,” has been used in sensitivity analyses to estimate the non-CO₂ benefits in previous EPA rulemakings (see U.S. EPA 2012, 2013).⁸⁴¹ EPA has not presented these

estimates in a main benefit-cost analysis due to the limitations associated with using the GWP approach to value changes in non-CO₂ GHG emissions, and considered the GWP approach as an interim method of analysis until social cost estimates for non-CO₂ GHGs, consistent with the SC-CO₂ estimates, were developed.

The GWP is a simple, transparent, and well-established metric for assessing the relative impacts of non-CO₂ emissions compared to CO₂ on a purely physical basis. However, as discussed both in the 2010 SC-CO₂ TSD and previous rulemakings (e.g., U.S. EPA 2012, 2013), the GWP approximation approach to measuring non-CO₂ GHG benefits has several well-documented limitations. These metrics are not ideally suited for use in benefit-cost analyses to approximate the social cost of non-CO₂ GHGs because the approach would assume all subsequent linkages leading to damages are linear in radiative

forcing, which would be inconsistent with the most recent scientific literature. Detailed discussion of limitations of the GWP approach can be found in the RIA.

EPA applies the GWP approach to estimate the benefits associated with reductions of HFCs in each calendar year. Under the GWP Approach, EPA converted HFC-134a to CO₂ equivalents using the AR4 100-year GWP for HFC-134a (1,430).⁸⁴² These CO₂-equivalent emission reductions are multiplied by the SC-CO₂ estimate corresponding to each year of emission reductions. As with the calculation of annual benefits of CO₂ emission reductions, the annual benefits of non-CO₂ emission reductions based on the GWP approach are discounted back to net present value terms using the same discount rate as each SC-CO₂ estimate. The estimated HFC-134a benefits using the GWP approach are presented in Table IX-16.

In determining the relative social costs of the different gases, the Marten et al. (2014) analysis accounts for differences in lifetime and radiative efficiency between the non-CO₂ GHGs and CO₂. The analysis also accounts for radiative forcing resulting from methane's effects on tropospheric ozone and stratospheric water vapor, and for at least some of the fertilization effects of elevated carbon dioxide concentrations. However, there exist several other differences between these gases that have not yet been captured in this analysis, for example the non-radiative effects of methane-driven elevated tropospheric ozone levels on human health, agriculture, and ecosystems, and the effects of carbon dioxide on ocean acidification. Inclusion of these additional non-radiative effects would potentially change both the absolute and relative value of the various gases.

Of these effects, the human health effect of elevated tropospheric ozone levels resulting from methane emissions is the closest to being monetized in a way that would be comparable to the SCC. Premature ozone-related cardiopulmonary deaths resulting from global increases in tropospheric ozone concentrations produced by the methane oxidation process have been the focus of a number of studies over the

past decade (*e.g.*, West et al. 2006;⁸⁴³ Anenberg et al. 2012;⁸⁴⁴ Shindell et al. 2012⁸⁴⁵). Recently, a paper was published in the peer-reviewed scientific literature that presented a range of estimates of the monetized ozone-related mortality benefits of reducing methane emissions (Sarofim et al. 2015). For example, under their base case assumptions using a 3 percent discount rate, Sarofim et al. find global ozone-related mortality benefits of methane emissions reductions to be \$790 per ton of methane in 2020, with 10.6 percent, or \$80, of this amount resulting from mortality reductions in the United States. The methodology used in this study is consistent in some (but not all) aspects with the modeling underlying the SC-CO₂ and SC-CH₄ estimates discussed above, and required a number of additional assumptions such as baseline mortality rates and

⁸⁴³ West JJ, Fiore AM, Horowitz LW, Mauzerall DL (2006) Global health benefits of mitigating ozone pollution with methane emission controls. *Proc Natl Acad Sci USA* 103 (11):3988–3993. doi:10.1073/pnas.0600201103

⁸⁴⁴ Anenberg SC, Schwartz J, Shindell D, Amann M, Faluvegi G, Klimont Z, . . . , Vignati E (2012) Global air quality and health co-benefits of mitigating near-term climate change through methane and black carbon emission controls. *Environ Health Perspect* 120 (6):831. doi:10.1289/ehp.1104301.

mortality response to ozone concentrations. While the EPA does consider the methane impacts on ozone to be important, there remain unresolved questions regarding several methodological choices involved in applying the Sarofim et al. (2015) approach in the context of an EPA benefits analysis, and therefore the EPA is not including a quantitative analysis of this effect in this rule at this time.

H. Monetized Non-GHG Health Impacts

This section discusses the economic benefits from reductions in health and environmental impacts resulting from non-GHG emission reductions that can be expected to occur as a result of the Phase 2 standards. CO₂ emissions are predominantly the byproduct of fossil fuel combustion processes that also produce criteria and hazardous air pollutant emissions. The vehicles that are subject to the Phase 2 standards are also significant sources of mobile source air pollution such as direct PM, NO_x, VOCs and air toxics. The standards will affect exhaust emissions of these pollutants from vehicles and will also affect emissions from upstream sources that occur during the refining and distribution of fuel. Changes in ambient concentrations of ozone, PM_{2.5}, and air toxics that will result from the Phase 2 standards are expected to affect human health by reducing premature deaths and other serious human health effects, as well as other important improvements in public health and

welfare. Children especially benefit from reduced exposures to criteria and toxic pollutants, because they tend to be more sensitive to the effects of these respiratory pollutants. Ozone and particulate matter have been associated with increased incidence of asthma and other respiratory effects in children, and particulate matter has been associated with a decrease in lung maturation. Some minority groups and children living under the poverty line are even more vulnerable with higher prevalence of asthma.

It is important to quantify the health and environmental impacts associated with the standards because a failure to adequately consider ancillary impacts could lead to an incorrect assessment of their costs and benefits. Moreover, the health and other impacts of exposure to criteria air pollutants and airborne toxics tend to occur in the near term, while most effects from reduced climate change are likely to occur only over a time frame of several decades or longer.

Impacts such as emissions reductions, costs and benefits are presented in this analysis from two perspectives:

- A “model year lifetime analysis” (MY), which shows impacts of the program that occur over the lifetime of the vehicles produced during the model years subject to the Phase 2 standards (MYs 2018 through 2029).,
- A “calendar year analysis” (CY), which shows annual costs and benefits of the Phase 2 standards for each year from 2018 through 2050. We assume the standard in the last model year subject to the standards applies to all subsequent MY fleets developed in the future.

In previous light-duty and heavy-duty GHG rulemakings, EPA has quantified and monetized non-GHG health impacts using two different methods. For the MY analysis, EPA applies PM-related “benefits per-ton” values to the stream of lifetime estimated emission reductions as a reduced-form approach to estimating the PM_{2.5}-related benefits of the rule.^{846 847} For the CY analysis, EPA typically conducts full-scale photochemical air quality modeling to quantify and monetize the PM_{2.5}- and

ozone-related health impacts of a single representative future year. EPA then assumes these benefits are repeated in subsequent future years when criteria pollutant emission reductions are equal to or greater than those modeled in the representative future year.

This two-pronged approach to estimating non-GHG impacts is precipitated by the length of time needed to prepare the necessary emissions inventories and the processing time associated with full-scale photochemical air quality modeling for a *single* representative future year. The timing requirements (along with other resource limitations) preclude EPA from being able to do the more detailed photochemical modeling for every year that we include in our benefit and cost estimates, and require EPA to make air quality modeling input decisions early in the analytical process. As a result, it was necessary to use emissions from the proposed program to conduct the air quality modeling.

The chief limitation when using air quality inventories based on emissions from the proposal in the CY modeling analysis is that they can diverge from the estimated emissions of the final rulemaking. How much the emissions might diverge and how that difference would impact the air quality modeling and health benefit results is difficult to anticipate. For the FRM, EPA concluded that when comparing the proposal and final rule inventories, the differences were enough to justify the move of the typical CY benefits analysis (based on air quality modeling) from the primary estimate of costs and benefits to a supplemental analysis in an appendix to the RIA (See RIA Appendix 8.A).⁸⁴⁸ While we believe this supplemental analysis is still illustrative of the standard’s potential benefits, EPA has instead chosen to characterize the CY benefits in a manner consistent with the MY lifetime analysis. That is, we apply the PM-related “benefits per-ton” values to the CY final rule emission reductions to estimate the PM-related benefits of the final rule.

This section presents the benefits-per-ton values used to monetize the benefits from reducing population exposure to PM associated with the standards. EPA bases its analyses on peer-reviewed studies of air quality and health and welfare effects and peer-reviewed studies of the monetary values of public health and welfare improvements, and is generally consistent with benefits analyses performed for the analysis of

the final Tier 3 Vehicle Rule,⁸⁴⁹ the final 2012 p.m. NAAQS Revision,⁸⁵⁰ and the final 2017–2025 Light Duty Vehicle GHG Rule.⁸⁵¹

EPA is also requiring that rebuilt engines installed in new incomplete vehicles (*i.e.*, “glider kit” vehicles) meet the emission standards applicable in the year of assembly of the new vehicle, including all applicable standards for criteria pollutants (Section XIII.B). For the final rule, EPA has updated its analysis of the environmental impacts of these glider kit vehicles (see Section XIII.B.1). These standards will decrease PM and NO_x emissions dramatically, leading to substantial public health-related benefits. Although we only present these benefits as a sensitivity analysis in Section XIII.B, it is clear that removing even a fraction of glider kit vehicles from the road will yield substantial health-related benefits that are not captured by the primary estimate of monetized non-GHG health impacts described in this section.

(1) Economic Value of Reductions in Particulate Matter

As described in Section VIII, the standards will reduce emissions of several criteria and toxic pollutants and their precursors. In this analysis, EPA only estimates the economic value of the human health benefits associated with the resulting reductions in PM_{2.5} exposure. Due to analytical limitations with the benefit per ton method, this analysis does not estimate benefits resulting from reductions in population exposure to other criteria pollutants such as ozone.⁸⁵² Furthermore, the

For more information regarding the updated values, see: http://www3.epa.gov/airquality/benmap/models/Source_Apportionment_BPT_TSD_1_31_13.pdf (accessed September 9, 2014).

⁸⁴⁸ Chapter 5 of the RIA has more detail on the differences between the air quality and final inventories.

benefits per-ton method, like all air quality impact analyses, does not monetize all of the potential health and welfare effects associated with reduced concentrations of PM_{2.5}.

This analysis uses estimates of the benefits from reducing the incidence of the specific PM_{2.5}-related health impacts described below. These estimates, which are expressed per ton of PM_{2.5}-related emissions eliminated by the final program, represent the monetized value of human health benefits (including reductions in both premature mortality and premature morbidity) from reducing each ton of directly emitted PM_{2.5} or its precursors (SO₂ and NO_x), from a specified source. Ideally, the human health benefits would be estimated based on changes in ambient

PM_{2.5} as determined by full-scale air quality modeling. However, the length of time needed to prepare the necessary emissions inventories, in addition to the processing time associated with the modeling itself, has precluded us from performing air quality modeling that reflects the emissions and air quality impacts associated with the final program.

EPA received comment regarding the omission of ozone-related benefits from the non-GHG benefits analysis included in the proposal. EPA agrees that total benefits are underestimated when ozone-related benefits are not included in the primary analysis. However, for reasons described in the introduction to this section, PM- and ozone-related health benefits based on air quality

modeling for the CY analysis are not included in the primary estimate of costs and benefits. Instead, they can be found as a supplemental analysis to the RIA in Appendix 8A.

The PM-related dollar-per-ton benefit estimates used in this analysis are provided in Table IX–17. As the table indicates, these values differ among pollutants, and also depend on their original source, because emissions from different sources can result in different degrees of population exposure and resulting health impacts. In the summary of costs and benefits, Section IX.K of this Preamble, EPA presents the monetized value of PM-related improvements associated with the final program.

TABLE IX–17—PM-RELATED BENEFITS-PER-TON VALUES
[Thousands, 2013\$]^a

Year ^c	On-road mobile sources			Upstream sources ^d		
	Direct PM _{2.5}	SO ₂	NO _x	Direct PM _{2.5}	SO ₂	NO _x
Estimated Using a 3 Percent Discount Rate^b						
2016	\$380–\$870	\$20–\$46	\$7.8–\$18	\$330–\$760	\$71–\$160	\$6.9–\$16
2020	410–920	22–50	8.2–18	350–800	76–170	7.5–17
2025	450–1,000	25–56	9.0–20	400–890	84–190	8.2–18
2030	490–1,100	28–62	9.7–22	430–960	92–200	8.9–20
Estimated Using a 7 Percent Discount Rate^b						
2016	\$340–\$780	\$18–\$42	\$7.1–\$16	\$300–\$680	\$64–\$140	\$6.3–\$14
2020	370–830	20–45	7.5–17	320–730	68–150	6.7–15
2025	410–920	22–50	8.1–18	350–800	76–170	7.4–17
2030	440–990	25–56	8.8–20	380–870	82–180	8.0–18

Notes:

^a The benefit-per-ton estimates presented in this table are based on a range of premature mortality estimates derived from the ACS study (Krewski et al., 2009) and the Six-Cities study (Lepeule et al., 2012). See Chapter VIII of the RIA for a description of these studies.

^b The benefit-per-ton estimates presented in this table assume either a 3 percent or 7 percent discount rate in the valuation of premature mortality to account for a twenty-year segmented premature mortality cessation lag.

^c Benefit-per-ton values were estimated for the years 2016, 2020, 2025 and 2030. We hold values constant for intervening years (e.g., the 2016 values are assumed to apply to years 2017–2019; 2020 values for years 2021–2024; 2030 values for years 2031 and beyond).

^d We assume for the purpose of this analysis that total “upstream emissions” are most appropriately monetized using the refinery sector benefit per-ton values. The majority of upstream emission reductions associated with the final rule are related to domestic onsite refinery emissions and domestic crude production. While total upstream emissions also include storage and transport sources, as well as sources upstream from the refinery, we have chosen to simply apply the refinery values.

The benefit-per-ton technique has been used in previous analyses, including EPA’s 2017–2025 Light-Duty Vehicle Greenhouse Gas Rule,⁸⁵³ the

Reciprocating Internal Combustion Engine rules,⁸⁵⁴ and the Residential Wood Heaters NSPS.⁸⁵⁶ Table IX–18 shows the quantified PM_{2.5}-related co-

benefits captured in those benefit per-ton estimates, as well as unquantified effects the benefit per-ton estimates are unable to capture.

per ton values. This limitation notwithstanding, we anticipate that the ozone-related benefits associated with reducing emissions of NO_x and VOC are substantial. Refer to RIA Appendix 8.A for the ozone benefits results from the supplemental CY benefits analysis.

TABLE IX-18—HUMAN HEALTH AND WELFARE EFFECTS OF PM_{2.5}

Pollutant/ effect	Quantified and monetized in primary estimates	Unquantified effects changes in:
PM _{2.5}	Adult premature mortality Acute bronchitis Hospital Admissions: Respiratory and cardiovascular Emergency room visits for asthma Nonfatal heart attacks (myocardial infarction) Lower and upper respiratory illness Minor restricted-activity days Work loss days Asthma exacerbations (asthmatic population). Infant mortality.	Chronic and subchronic bronchitis cases. Strokes and cerebrovascular disease. Low birth weight. Pulmonary function. Chronic respiratory diseases other than chronic bronchitis. Non-asthma respiratory emergency room visits. Visibility. Household soiling.

A more detailed description of the benefit-per-ton estimates is provided in Chapter 8 of the RIA that accompanies this rulemaking. Readers interested in reviewing the complete methodology for creating the benefit-per-ton estimates used in this analysis can consult EPA's "Technical Support Document: Estimating the Benefit per Ton of Reducing PM_{2.5} Precursors from 17 Sectors."⁸⁵⁷ Readers can also refer to Fann et al. (2012)⁸⁵⁸ for a detailed description of the benefit-per-ton methodology.

As Table IX-17 indicates, EPA projects that the per-ton values for reducing emissions of non-GHG pollutants from both vehicle use and upstream sources such as fuel refineries will increase over time.⁸⁵⁹ These projected increases reflect rising income levels, which increase affected individuals' willingness to pay for reduced exposure to health threats from air pollution.⁸⁶⁰ They also reflect future population growth and increased life expectancy, which expands the size of the population exposed to air pollution in both urban and rural areas, especially

among older age groups with the highest mortality risk.⁸⁶¹

(2) Unquantified Health and Environmental Impacts

One commenter supported the inclusion of all quantifiable impacts of reductions in non-GHG pollutants. Specifically, they suggested the inclusion of ecosystem benefits from reduced non-GHG pollutants including those to crops as well as consideration of the impacts on toxic air contaminants such as diesel PM.

In addition to the PM-related co-pollutant health impacts EPA quantifies in this analysis, EPA acknowledges that there are a number of other health and human welfare endpoints that we are not able to quantify or monetize because of current limitations in the methods or available data. These impacts are associated with emissions of air toxics (including benzene, 1,3-butadiene, formaldehyde, acetaldehyde, acrolein, naphthalene and ethanol), ambient ozone, and ambient PM_{2.5} exposures. Chapter 8 of the RIA lists these unquantified health and environmental impacts. While there will be impacts associated with air toxic pollutant emission changes that result from the final standard, EPA will not attempt to monetize those impacts. This is primarily because currently available tools and methods to assess air toxics risk from mobile sources at the national scale are not adequate for extrapolation to incidence estimations or benefits assessment. The best suite of tools and methods currently available for assessment at the national scale are those used in the National-Scale Air Toxics Assessment (NATA). EPA's Science Advisory Board specifically commented in their review of the 1996 NATA that these tools were not yet ready for use in a national-scale benefits

analysis, because they did not consider the full distribution of exposure and risk, or address sub-chronic health effects.⁸⁶² While EPA has since improved the tools, there remain critical limitations for estimating incidence and assessing benefits of reducing mobile source air toxics.⁸⁶³ EPA continues to work to address these limitations; however, EPA does not have the methods and tools available for national-scale application in time for the analysis of the final rules.⁸⁶⁴

I. Energy Security Impacts

The Phase 2 standards are designed to require improvements in the fuel efficiency of medium- and heavy-duty vehicles and, thereby, reduce fuel consumption and GHG emissions. In turn, the Phase 2 standards help to reduce U.S. petroleum imports. A reduction of U.S. petroleum imports reduces both financial and strategic risks caused by potential sudden disruptions in the supply of imported petroleum to the U.S., thus increasing

⁸⁵⁷ For more information regarding the updated values, see: http://www3.epa.gov/airquality/benmap/models/Source_Apportionment_BPT_TSD_1_31_13.pdf (accessed September 9, 2014).

⁸⁵⁹ As we discuss in the emissions chapter of the RIA (Chapter V), the rule will yield emission reductions from upstream refining and fuel distribution due to decreased petroleum consumption.

⁸⁶⁰ The issue is discussed in more detail in the 2012 p.m. NAAQS RIA. See U.S. Environmental Protection Agency. (2012). *Regulatory Impact Analysis for the Final Revisions to the National Ambient Air Quality Standards for Particulate Matter*, Health and Environmental Impacts Division, Office of Air Quality Planning and Standards, EPA-452-R-12-005, December 2012. Available on the internet: <http://www3.epa.gov/ttnecas1/regdata/RIAs/finalria.pdf>.

⁸⁶¹ For more information about EPA's population projections, please refer to the following: <http://www3.epa.gov/air/benmap/models/BenMAPManualAppendicesAugust2010.pdf> (See Appendix K).

⁸⁶² Science Advisory Board. 2001. NATA—Evaluating the National-Scale Air Toxics Assessment for 1996—an SAB Advisory. <http://www3.epa.gov/ttn/atw/sab/sabrev.html>.

⁸⁶³ Examples include gaps in toxicological data, uncertainties in extrapolating results from high-dose animal experiments to estimate human effects at lower doses, limited ambient and personal exposure monitoring data, and insufficient economic research to support valuation of the health impacts often associated with exposure to individual air toxics. See Gwinn et al., 2011. Meeting Report: Estimating the Benefits of Reducing Hazardous Air Pollutants—Summary of 2009 Workshop and Future Considerations. *Environ Health Perspectives*, Jan 2011; 119(1): 125–130.

⁸⁶⁴ In April, 2009, EPA hosted a workshop on estimating the benefits of reducing hazardous air pollutants. This workshop built upon the work accomplished in the June 2000 in an earlier (2000) Science Advisory Board/EPA Workshop on the Benefits of Reductions in Exposure to Hazardous Air Pollutants, which generated thoughtful discussion on approaches to estimating human health benefits from reductions in air toxics exposure, but no consensus was reached on methods that could be implemented in the near term for a broad selection of air toxics. Please visit <http://epa.gov/air/toxicair/2009workshop.html> for more information about the workshop and its associated materials.

U.S. energy security. This section summarizes the agency's estimates of U.S. oil import reductions and energy security benefits of the Phase 2 final standards. Additional discussion of this issue can be found in Chapter 8.8 of the RIA.

(1) Implications of Reduced Petroleum Use on U.S. Imports

U.S. energy security is generally considered as the continued availability of energy sources at an acceptable price. Most discussion of U.S. energy security revolves around the topic of the economic costs of U.S. dependence on oil imports. While the U.S. has reduced its consumption and increased its production of oil in recent years, it still relies on oil from potentially unstable sources. In addition, oil exporters with a large share of global production have the ability to raise the price of oil by exerting the monopoly power associated with a cartel, the Organization of Petroleum Exporting Countries (OPEC), to restrict oil supply relative to demand. These factors contribute to the vulnerability of the U.S. economy to episodic oil supply shocks and price spikes.

In 2014, U.S. expenditures for imports of crude oil and petroleum products, net of revenues for exports, were \$178 billion and expenditures on both imported oil and domestic petroleum and refined products totaled \$469 billion (in 2013\$) (see Figure IX-1).⁸⁶⁵ Recently, as a result of strong growth in domestic oil production mainly from tight shale formations, U.S. production of oil has increased while U.S. oil imports have decreased. For example, from 2012 to 2015, domestic oil production increased by 44 percent while net oil imports and products decreased by 38 percent. While U.S. oil

import costs have declined since 2011, total oil expenditures (domestic and imported) remained near historical highs through 2014. Post-2015 oil expenditures are projected (AEO 2015) to remain between double and triple the inflation-adjusted levels experienced by the U.S. from 1986 to 2002.C

Focusing on changes in oil import levels as a source of vulnerability has been standard practice in assessing energy security in the past, but given current market trends both from domestic and international levels, adding changes in consumption of petroleum to this assessment may provide better information about U.S. energy security. The major mechanism through which the economy sustains harm due to fluctuations in the (world) energy market is through price, which itself is leveraged through both imports and consumption. However, the United States, may be increasingly insulated from the physical effects of overseas oil disruptions, though the price impacts of an oil disruption anywhere will continue to be transmitted to U.S. markets. As of 2015, Canada accounted for 63 percent of U.S. net oil imports of crude oil and petroleum products. The implications of the U.S. becoming a significant petroleum producer have yet to be discerned in the literature, but it can be anticipated that this will have some impact on energy security.

In 2010, just over 40 percent of world oil supply came from OPEC nations. The AEO 2015 projects that this share will stay high; dipping slightly from 37 percent by 2020 and then rising gradually to over 40 percent by 2035 and thereafter. Approximately 30 percent of global supply is from Middle East and North African countries alone, a share that is also expected to grow. Measured in terms of the share of world oil resources or the share of global oil export supply, rather than oil production, the concentration of global petroleum resources in OPEC nations is

even larger. As another measure of concentration, of the 137 countries/principalities that export either crude or refined products, the top 12 have recently accounted for over 55 percent of exports.⁸⁶⁶ Eight of these countries are members of OPEC, and a ninth is Russia.⁸⁶⁷ In a market where even a 1–2 percent supply loss can raise prices noticeably, and where a 10 percent supply loss could lead to an unprecedented price shock, this regional concentration is of concern.⁸⁶⁸ Historically, the countries of the Middle East have been the source of eight of the ten major world oil disruptions,⁸⁶⁹ with the ninth originating in Venezuela, an OPEC country, and the tenth being Hurricanes Katrina and Rita.

⁸⁶⁶ Based on data from the CIA, combining various recent years, <https://www.cia.gov/library/publications/the-world-factbook/rankorder/2242rank.html>.

⁸⁶⁷ The other three are Norway, Canada, and the EU, an exporter of product.

⁸⁶⁸ For example, the 2005 Hurricanes Katrina/Rita and the 2011 Libyan conflict both led to a 1.8 percent reduction in global crude supply. While the price impact of the latter is not easily distinguished given the rapidly rising post-recession prices, the former event was associated with a 10–15 percent world oil price increase. There are a range of smaller events with smaller but noticeable impacts. Somewhat larger events, such as the 2002/3 Venezuelan Strike and the War in Iraq, corresponded to about a 2.9 percent sustained loss of supply, and were associated with a 28 percent world oil price increase.

Compiled from EIA oil price data, IEA2012 [IEA Response System for Oil Supply Emergencies (http://www.iea.org/publications/freepublications/publication/EPPD_Brochure_English_2012_02.pdf)

⁸⁶⁵ See EIA Annual Energy Review, various editions. For data 2011–2013, and projected data: EIA Annual Energy Outlook (AEO) 2014 (Reference Case). See Table 11, file “aetotab_11.xls.”

Figure IX-1 U.S. Expenditures on Crude Oil from 1970 through 2015⁸⁷⁰

The agencies used EPA's MOVES model to estimate the reductions in U.S. fuel consumption due to these final rules for vocational vehicles and tractors. For HD pickups and vans, the agencies used both DOT's CAFE model and EPA's MOVES model to estimate the fuel consumption impacts. (Detailed explanations of the MOVES and CAFE models can be found in Chapter 5 of the RIA. See IX.C of the Preamble for estimates of reduced fuel consumption from these final rules). Based on a detailed analysis of differences in U.S. fuel consumption, petroleum imports, and imports of petroleum products, the

agencies estimate that approximately 90 percent of the reduction in fuel consumption resulting from adopting improved GHG emission and fuel efficiency standards is likely to be reflected in reduced U.S. imports of crude oil and net imported petroleum products.⁸⁷¹ Thus, on balance, each gallon of fuel saved as a consequence of the HD GHG and fuel efficiency standards is anticipated to reduce total U.S. imports of petroleum by 0.90 gallons. Based upon the fuel savings estimated by the MOVES/CAFE models and the 90 percent oil import factor, the reduction in U.S. oil imports and

exports from these final rules are estimated for the years 2020, 2025, 2030, 2040, and 2050 (in millions of barrels per day (MMBD)) in Table IX-19 below. For comparison purposes, Table IX-19 also shows U.S. imports of crude oil in 2020, 2025, 2030 and 2040 as projected by DOE in the Annual Energy Outlook 2015 Reference Case. U.S. Gross Domestic Product (GDP) is projected to grow by roughly 48 percent over the same time frame (e.g., from 2020 to 2040) in the AEO 2015 projections.

TABLE IX-19—PROJECTED U.S. IMPORTS AND EXPORTS OF OIL AND U.S. OIL IMPORT REDUCTIONS RESULTING FROM THE FINAL PHASE 2 PROGRAM IN 2020, 2025, 2030, 2040 AND 2050 USING METHOD B AND RELATIVE TO A FLAT BASELINE

[Millions of barrels per day (MMBD)]^a

Year	U.S. oil exports	U.S. oil imports	U.S. net product imports *	U.S. net crude & product imports	U.S. oil import reductions from final HD Rules
2020	0.63	6.14	- 2.80	2.71	0.007
2025	0.63	6.72	- 3.24	2.85	0.162
2030	0.63	7.07	- 3.56	2.88	0.405
2040	0.63	8.21	- 4.26	3.32	0.721

⁸⁷⁰ We looked at changes in U.S. crude oil imports and net petroleum products in the AEO 2015 Reference Case in comparison to the Low (*i.e.*, Economic Growth) Demand Case to undertake this analysis. See the spreadsheet "Impact of Fuel

Demand on Imports AEO2015.xlsx." We also considered a paper entitled "Effect of a U.S. Demand Reduction on Imports and Domestic Supply Levels" by Leiby, P., 4/16/2013. This paper suggests that "Given a particular reduction in oil

demand stemming from a policy or significant technology change, the fraction of oil use savings that shows up as reduced U.S. imports, rather than reduced U.S. supply, is actually quite close to 90 percent, and probably close to 95 percent."

TABLE IX-19—PROJECTED U.S. IMPORTS AND EXPORTS OF OIL AND U.S. OIL IMPORT REDUCTIONS RESULTING FROM THE FINAL PHASE 2 PROGRAM IN 2020, 2025, 2030, 2040 AND 2050 USING METHOD B AND RELATIVE TO A FLAT BASELINE—Continued

[Millions of barrels per day (MMBD)]^a

Year	U.S. oil exports	U.S. oil imports	U.S. net product imports *	U.S. net crude & product imports	U.S. oil import reductions from final HD Rules
2050	(**)	(**)	(**)	(**)	0.861

Notes:

* Negative U.S. Net Product Imports imply positive exports.

** The AEO 2015 only projects energy market and economic trends through 2040.

(2) Energy Security Implications

In order to understand the energy security implications of reducing U.S. oil imports, EPA has worked with Oak Ridge National Laboratory (ORNL), which has developed approaches for evaluating the social costs and energy security implications of oil use. The energy security estimates provided below are based upon a methodology developed in a peer-reviewed study entitled, “*The Energy Security Benefits of Reduced Oil Use, 2006–2015*”, completed in March 2008. This ORNL study is an updated version of the approach used for estimating the energy security benefits of U.S. oil import reductions developed in a 1997 ORNL Report.⁸⁷² For EPA and NHTSA rulemakings, the ORNL methodology is updated periodically to account for forecasts of future energy market and economic trends reported in the U.S. Energy Information Administration’s Annual Energy Outlook.

When conducting this analysis, ORNL considered the full cost of importing petroleum into the U.S. The full economic cost is defined to include two components in addition to the purchase price of petroleum itself. These are: (1) The higher costs for oil imports resulting from the effect of U.S. demand on the world oil price (*i.e.*, the

“demand” or “monopsony” costs); and (2) the risk of reductions in U.S. economic output and disruption to the U.S. economy caused by sudden disruptions in the supply of imported oil to the U.S. (*i.e.*, macroeconomic disruption/adjustment costs).

The literature on energy security for the last two decades has routinely combined the monopsony and the macroeconomic disruption components when calculating the total value of the energy security premium. However, in the context of using a global value for the Social Cost of Carbon (SCC) the question arises: how should the energy security premium be used when some benefits from these rules, such as the benefits of reducing greenhouse gas emissions, are calculated from a global perspective? Monopsony benefits represent avoided payments by U.S. consumers to oil producers that result from a decrease in the world oil price as the U.S. decreases its demand for oil. Although there is clearly an overall benefit to the U.S. when considered from a domestic perspective, the decrease in price due to decreased demand in the U.S. also represents a loss to oil producing countries, one of which is the U.S. Given the redistributive nature of this monopsony effect from a global perspective, it is

excluded in the energy security benefits calculations for these final rules.

In contrast, the other portion of the energy security premium, the avoided U.S. macroeconomic disruption and adjustment cost that arises from reductions in U.S. petroleum imports, does not have offsetting impacts outside of the U.S., and, thus, is included in the energy security benefits estimated for these final rules. To summarize, the agencies have included only the avoided macroeconomic disruption portion of the energy security benefits to estimate the monetary value of the total energy security benefits of these final rules.

For this rulemaking, ORNL updated the energy security premiums by incorporating the most recent oil price forecast and energy market trends, particularly regional oil supplies and demands, from the AEO 2015 into its model.⁸⁷³ ORNL developed energy security premium estimates for a number of different years. Table IX-20 provides estimates for energy security premiums for the years 2020, 2025, 2030 and 2040,⁸⁷⁴ as well as a breakdown of the components of the energy security premiums for each year. The components of the energy security premiums and their values are discussed below.

TABLE IX-20—ENERGY SECURITY PREMIUMS IN 2020, 2025, 2030 AND 2040

[2013\$/Barrel] *

Year (range)	Monopsony (range)	Avoided macroeconomic disruption/adjustment costs (range)	Total mid-point (range)
2020	\$2.21 (\$0.65–\$3.59)	\$5.48 (\$2.51–\$8.92)	\$7.69 (\$4.54–\$11.14)
2025	\$2.59 (\$0.76–\$4.14)	\$6.30 (\$2.92–\$10.22)	\$8.89 (\$5.22–\$12.83)
2030	\$2.83 (0.83–\$4.56)	\$7.26 (\$3.40–\$11.73)	\$10.09 (\$5.90–\$14.59)

(a) Effect of Oil Use on the Long-Run Oil Price

The first component of the full economic costs of importing petroleum into the U.S. follows from the effect of U.S. import demand on the world oil price over the long-run. Because the U.S. is a sufficiently large purchaser of global oil supplies, its purchases can affect the world oil price. This monopsony power means that increases in U.S. petroleum demand can cause the world price of crude oil to rise, and conversely, that reduced U.S. petroleum demand can reduce the world price of crude oil. Thus, one benefit of decreasing U.S. oil purchases, due to improvements in the fuel efficiency of medium- and heavy-duty vehicles, is the potential decrease in the crude oil price paid for all crude oil purchased.

There is disagreement in the literature about the magnitude of the monopsony component, and its relevance for policy analysis. Brown and Huntington (2013)⁸⁷⁵ for example, argue that the United States' refusal to exercise its market power to reduce the world oil price does not represent a proper externality, and that the monopsony component should not be considered in calculations of the energy security externality. However, they also note in their earlier discussion paper (Brown and Huntington 2010)⁸⁷⁶ that this is a departure from the traditional energy security literature, which includes sustained wealth transfers associated with stable but higher-price oil markets. On the other hand, Greene (2010)⁸⁷⁷ and others in prior literature (e.g., Toman 1993)⁸⁷⁸ have emphasized that

the monopsony cost component is policy-relevant because the world oil market is non-competitive and strongly influenced by cartelized and government-controlled supply decisions. Thus, while sometimes couched as an externality, Greene notes that the monopsony component is best viewed as stemming from a completely different market failure than an externality (Ledyard 2008),⁸⁷⁹ yet still implying marginal social costs to importers.

Recently, the Council on Foreign Relations (i.e., "the Council") (2015) released a discussion paper that assesses NHTSA's analysis of the benefits and costs of CAFE in a lower-oil-price world.⁸⁸⁰ In this paper, the Council notes that while NHTSA cites the monopsony effect of the CAFE standards for 2017–2025, NHTSA does not include it when calculating the cost-benefit calculation for the rule. The Council argues that the monopsony benefit should be included in the CAFE cost-benefit analysis and that including the monopsony benefit is more consistent with the legislators' intent in mandating CAFE standards in the first place.

The recent National Academy of Science (NAS 2015) Report, "Cost, Effectiveness and the Deployment of Fuel Economy Technologies for Light-Duty Vehicles,"⁸⁸¹ suggests that the agencies' logic about not accounting for monopsony benefits is inaccurate. According to the NAS, the fallacy lies in treating the two problems, oil dependence and climate change, similarly. According to the NAS, "Like national defense, it [oil dependence] is inherently adversarial (i.e., oil consumers against producers using

monopoly power to raise prices). The problem of climate change is inherently global and requires global action. If each nation considered only the benefits to itself in determining what actions to take to mitigate climate change, an adequate solution could not be achieved. Likewise, if the U.S. considers the economic harm its reduced petroleum use will do to monopolistic oil producers it will not adequately address its oil dependence problem. Thus, if the United States is to solve both of these problems it must take full account of the costs and benefits of each, using the appropriate scope for each problem." At this point in time, we are continuing to exclude monopsony premiums for the cost benefit analysis of these final rules, but we will be taking comment on this issue in a near term future rulemaking.

There is also a question about the ability of gradual, long-term reductions, such as those resulting from these final rules, to reduce the world oil price in the presence of OPEC's monopoly power. OPEC is currently the world's marginal petroleum supplier, and could conceivably respond to gradual reductions in U.S. demand with gradual reductions in supply over the course of several years as the fuel savings resulting from these rules grow. However, if OPEC opts for a long-term strategy to preserve its market share, rather than maintain a particular price level (as they have done recently in response to increasing U.S. petroleum production), reduced demand will create downward pressure on the global price. The Oak Ridge analysis assumes that OPEC does respond to demand reductions over the long run, but there is still a price effect in the model. Under the mid-case behavioral assumption used in the premium calculations, OPEC responds by gradually reducing supply to maintain *market share* (consistent with the long-term self-interested strategy suggested by Gately (2004, 2007)).⁸⁸²

(b) Macroeconomic Disruption Adjustment Costs

The second component of the oil import premium, “avoided macroeconomic disruption/adjustment costs,” arises from the effect of oil imports on the expected cost of supply disruptions and accompanying price increases. A sudden increase in oil prices triggered by a disruption in world oil supplies has two main effects: (1) It increases the costs of oil imports in the short-run and (2) it can lead to macroeconomic contraction, dislocation and Gross Domestic Product (GDP) losses. For example, ORNL estimates the combined value of these two factors to be \$6.30/barrel (2013\$) when U.S. oil imports are reduced in 2025, with a range from \$2.92/barrel to \$10.22/barrel of imported oil reduced.

Since future disruptions in foreign oil supplies are an uncertain prospect, each of the disruption cost components must be weighted by the probability that the supply of petroleum to the U.S. will actually be disrupted. Thus, the “expected value” of these costs—the product of the probability that a supply disruption will occur and the sum of costs from reduced economic output and the economy’s abrupt adjustment to sharply higher petroleum prices—is the relevant measure of their magnitude. Further, when assessing the energy security value of a policy to reduce oil use, it is only the change in the expected costs of disruption that results from the policy that is relevant. The expected costs of disruption may change from lowering the normal (*i.e.*, pre-disruption) level of domestic petroleum use and imports, from any induced alteration in the likelihood or size of disruption, or from altering the short-run flexibility (*e.g.*, elasticity) of petroleum use.

By late 2015/early 2016, world oil prices were sharply lower than in 2014. Future prices remain uncertain, but sustained markedly lower oil prices can have mixed implications for U.S. energy security. Under lower prices U.S. expenditures on oil consumption are lower, and they are a less prominent component of the U.S. economy. This would lessen the issue of imported oil as an energy security problem for the U.S. On the other hand, sustained lower oil prices encourage greater oil consumption, and reduce the competitiveness of new U.S. oil supplies and alternative fuels. The AEO 2015 low oil price outlook, for example, projects that by 2030 total U.S.

petroleum supply would be 10 percent lower and imports would be 78 percent higher than the AEO Reference Case. Under the low-price case, 2030 prices are 35 percent lower, so that import expenditures are 16 percent higher.

A second potential proposed energy security effect of lower oil prices is increased instability of supply, due to greater global reliance on fewer supplying nations,⁸⁸³ and because lower prices may increase economic and geopolitical instability in some supplier nations.^{884 885 886} The International Monetary Fund reported that low oil prices are creating substantial economic tension in the Middle East oil producers on top of the economic costs of ongoing conflicts, and noted the risk that Middle East countries including Saudi Arabia could run out of financial assets without substantial change in policy.⁸⁸⁷ The concern raised is that oil revenues are essential for some exporting nations to fund domestic programs and avoid domestic unrest.

The Competitive Enterprise Institute (CEI) and others argue that there are little, if any, energy security benefits associated with these rules. In large part CEI argues that oil supplies are plentiful and that current oil prices are low so that reduced consumption of petroleum

products due to these rules would have no effect on energy security. However, the discussion of current low oil prices (“lowest Labor Day gasoline prices in a decade”) does not assure the absence of future oil supply shocks or price shocks, or even speak to their reduced likelihood. CEI points out that the current low oil prices have been observed before as recently as a decade ago, as they have in more than one instance before that. For example, oil prices were even lower in 1999. But in the intervening periods, oil supply and price shocks have continued to recur, and the recent price record only amplifies oil’s high historical price volatility.

Also, sharply lower world oil prices do not clearly imply greater energy security for the U.S. Current low world oil prices may reduce the U.S.’s fracking industry’s tight oil production (as CEI points out), or other sources of oil supplies around the world. Some have hypothesized that reduction in oil production outside of OPEC may be the objective of some OPEC producers. With low oil prices, U.S.’ oil import share over time might be larger, increasing the U.S.’ dependence on imported oil.

Securing America’s Future Energy (SAFE), Operation Free and the Investor Network on Climate Risk agree that these rules do improve America’s energy security. SAFE goes on to state that several policy options should be included in these rules to further enhance energy security. The agencies agree that these rules enhance America’s energy security, but do not have information to evaluate the policy options that SAFE proposes.

The recent economics literature on whether oil shocks are the threat to economic stability that they once were is mixed. Some of the current literature asserts that the macroeconomic component of the energy security externality is small. For example, the National Research Council (2009) argued that the non-environmental externalities associated with dependence on foreign oil are small, and potentially trivial.⁸⁸⁸ Analyses by Nordhaus (2007) and Blanchard and Gali (2010) question the impact of more recent oil price shocks on the economy.⁸⁸⁹ They were motivated by

⁸⁸³ Fatih Birol, Executive Director of the International Energy Agency, warns that prolonged lower oil prices would trigger energy security concerns by increasing reliance on a small number of low-cost producers “or risk a sharp rebound in price if investment falls short.” “It would be a grave mistake to index our attention to energy security to changes in the oil price,” Birol said. “Now is not the time to relax. Quite the opposite: a period of low oil prices is the moment to reinforce our capacity to deal with future energy security threats.” Hussain, Y. (2015). “Grave mistake” to be complacent on energy security, International Energy Agency warns. *Financial Post*, (November 10). attempts to explain why the economy actually expanded immediately after the last shocks, and why there was no evidence of higher energy prices being passed on through higher wage inflation. Using different methodologies, they conclude that the economy has largely gotten over its concern with dramatic swings in oil prices.

One reason, according to Nordhaus, is that monetary policy has become more accommodating to the price impacts of oil shocks. Another is that consumers have simply decided that such movements are temporary, and have noted that price impacts are not passed on as inflation in other parts of the economy. He also notes that real changes to productivity due to oil price increases are incredibly modest,⁸⁹⁰ and that the general direction of the economy matters a great deal regarding how the economy responds to a shock. Estimates of the impact of a price shock on aggregate demand are insignificantly different from zero.

Blanchard and Gali (2010) contend that improvements in monetary policy (as noted above), more flexible labor markets, and lessening of energy intensity in the economy, combined with an absence of concurrent shocks, all contributed to lessen the impact of oil shocks after 1980. They find “. . . the effects of oil price shocks have changed over time, with steadily smaller effects on prices and wages, as well as on output and employment.”⁸⁹¹ In a comment at the chapter's end, this work is summarized as follows: “The message of this chapter is thus optimistic in that it suggests a transformation in U.S. institutions has inoculated the economy against the responses that we saw in the past.”

At the same time, the implications of the “Shale Oil Revolution” are now being felt in the international markets, with current prices at four year lows. Analysts generally attribute this result in part to the significant increase in supply resulting from U.S. production, which has put liquid petroleum production roughly on par with Saudi Arabia. The price decline is also

attributed to the sustained reductions in U.S. consumption and global demand growth from fuel efficiency policies and previously high oil prices. The resulting decrease in foreign imports, down to about one-third of domestic consumption (from 60 percent in 2005, for example⁸⁹²), effectively permits U.S. supply to act as a buffer against artificial or other supply restrictions (the latter due to conflict or a natural disaster, for example).

However, other papers suggest that oil shocks, particularly sudden supply shocks, remain a concern. Both Blanchard and Gali's and Nordhaus work were based on data and analysis through 2006, ending with a period of strong global economic growth and growing global oil demand. The Nordhaus work particularly stressed the effects of the price increase from 2002–2006 that were comparatively gradual (about half the growth rate of the 1973 event and one-third that of the 1990 event). The Nordhaus study emphasizes the robustness of the U.S. economy during a time period through 2006. This time period was just before rapid further increases in the price of oil and other commodities with oil prices more-than-doubling to over \$130/barrel by mid-2008, only to drop after the onset of the largest recession since the Great Depression.

Hamilton (2012) reviewed the empirical literature on oil shocks and suggested that the results are mixed, noting that some work (e.g. Rasmussen and Roitman (2011) finds less evidence for economic effects of oil shocks, or declining effects of shocks (Blanchard and Gali 2010), while other work continues to find evidence regarding the economic importance of oil shocks. For example, Baumeister and Peersman (2011) found that an oil price increase had a decreasing effect over time. But they note that with a declining price-elasticity of demand that a given physical oil disruption would have a bigger effect on price and a similar effect on output as in the earlier data.⁸⁹³ Hamilton observes that “a negative effect of oil prices on real output has also been reported for a number of other countries, particularly when nonlinear functional forms have been employed”. Alternatively, rather than a declining

effect, Ramey and Vine (2010)⁸⁹⁴ found “remarkable stability in the response of aggregate real variables to oil shocks once we account for the extra costs imposed on the economy in the 1970s by price controls and a complex system of entitlements that led to some rationing and shortages.”

Some of the recent literature on oil price shocks has emphasized that economic impacts depend on the nature of the oil shock, with differences between price increases caused by sudden supply loss and those caused by rapidly growing demand. Most recent analyses of oil price shocks have confirmed that “demand-driven” oil price shocks have greater effects on oil prices and tend to have positive effects on the economy while “supply-driven” oil shocks still have negative economic impacts (Baumeister, Peersman and Van Robays (2010)).⁸⁹⁵ A recent paper by Kilian and Vigfusson (2014),⁸⁹⁶ for example, assigned a more prominent role to the effects of price increases that are unusual, in the sense of being beyond range of recent experience. Kilian and Vigfusson also conclude that the difference in response to oil shocks may well stem from the different effects of demand- and supply-based price increases: “One explanation is that oil price shocks are associated with a range of oil demand and oil supply shocks, some of which stimulate the U.S. economy in the short run and some of which slow down U.S. growth (see Kilian (2009)). How recessionary the response to an oil price shock is thus depends on the average composition of oil demand and oil supply shocks over the sample period.”

The general conclusion that oil supply-driven shocks reduce economic output is also reached in a recently published paper by Cashin et al. (2014)⁸⁹⁷ for 38 countries from 1979–2011. “The results indicate that the economic consequences of a supply-driven oil-price shock are very different from those of an oil-demand shock

1970s?”, pp. 373–421, in *The International Dimensions of Monetary Policy*, Jordi Gali and Mark Gertler, editors, University of Chicago Press, February 2010, available at <http://www.nber.org/chapters/c0517.pdf>.

⁸⁹⁰ In fact, “. . . energy-price changes have no effect on multifactor productivity and very little effect on labor productivity.” Page 19. He calculates the productivity effect of a doubling of oil prices as a decrease of 0.11 percent for one year and 0.04 percent a year for ten years. Page 5. (The doubling reflects the historical experience of the post-war shocks, as described in Table 7.1 in Blanchard and Gali, p. 380).

driven by global economic activity, and vary for oil-importing countries compared to energy exporters,” and “oil importers [including the U.S.] typically face a long-lived fall in economic activity in response to a supply-driven surge in oil prices” but almost all countries see an increase in real output for an oil-demand disturbance. Note that the energy security premium calculation in this analysis is based on price shocks from potential future supply events only.

Finally, despite continuing uncertainty about oil market behavior and outcomes and the sensitivity of the U.S. economy to oil shocks, it is generally agreed that it is beneficial to reduce petroleum fuel consumption from an energy security standpoint. It is not just imports alone, but both imports and consumption of petroleum from all sources and their role in economic activity, that may expose the U.S. to risk from price shocks in the world oil price. Reducing fuel consumption reduces the amount of domestic economic activity associated with a commodity whose price depends on volatile international markets.

(c) Cost of Existing U.S. Energy Security Policies

The last often-identified component of the full economic costs of U.S. oil imports are the costs to the U.S. taxpayers of existing U.S. energy security policies. The two primary examples are maintaining the Strategic Petroleum Reserve (SPR) and maintaining a military presence to help secure a stable oil supply from potentially vulnerable regions of the world. The SPR is the largest stockpile of government-owned emergency crude oil in the world. Established in the aftermath of the 1973/1974 oil embargo, the SPR provides the U.S. with a response option should a disruption in commercial oil supplies threaten the U.S. economy. It also allows the U.S. to meet part of its International Energy Agency obligation to maintain emergency oil stocks, and it provides a national defense fuel reserve. While the costs for building and maintaining the SPR are more clearly related to U.S. oil use and imports, historically these costs have not varied in response to changes in U.S. oil import levels. Thus, while the effect of the SPR in moderating price shocks is factored into the ORNL analysis, the cost of maintaining the SPR is excluded.

U.S. military costs are excluded from the analysis performed by ORNL because their attribution to particular missions or activities is difficult, and because it is not clear that these outlays

would decline in response to incremental reductions in U.S. oil imports. Most military forces serve a broad range of security and foreign policy objectives. The agencies also recognize that attempts to attribute some share of U.S. military costs to oil imports are further challenged by the need to estimate how those costs might vary with incremental variations in U.S. oil imports.

In the proposal to these rules, the agencies solicited comments on quantifying the military benefits from reduced U.S. imports of oil. The California Air Resources Board (CARB) notes that the National Research Council (NRC)⁸⁹⁸ attempted to estimate the military costs associated with U.S. imports and consumption of petroleum. The NRC cited estimates of the national defense costs of oil dependence from the literature that range from less than \$5 to \$50 billion per year or more. Assuming a range of approximate range of \$10 to \$50 billion per year, the NRC divided national defense costs by a projected U.S. consumption rate of approximately 6.4 billion barrels per year (EIA, 2012). This procedure yielded a range of average national defense cost of \$1.50–\$8.00 per barrel (rounded to the nearest \$0.50), with a mid-point of \$5/barrel (in 2009\$). The agencies acknowledge this NRC study, but have not included the estimates as part of the cost-benefit analysis for these rules.

(3) Energy Security Benefits of This Program

Using the ORNL “oil premium” methodology, updating world oil price values and energy trends using AEO 2015 and using the estimated fuel savings from these final rules estimated from the MOVES/CAFE models, the agencies have calculated the annual energy security benefits of these final rules through 2050.⁸⁹⁹ Since the agencies are taking a global perspective with respect to valuing greenhouse gas benefits from the rules, only the avoided macroeconomic adjustment/disruption portion of the energy security premium is used in the energy security benefits estimates present below. These results are shown below in Table IX–21. The agencies have also calculated the net present value at 3 percent and 7 percent discount rates of model year lifetime benefits associated with energy security;

⁸⁹⁸ National Research Council, “Transitions to alternative vehicles and fuels,” 2013.

⁸⁹⁹ In order to determine the energy security benefits beyond 2040, we use the 2040 energy security premium multiplied by the estimate fuel savings from the final rule. Since the AEO 2015 only goes to 2040, we only calculate energy security premiums to 2040.

these values are presented in Table IX–22.

J. Other Impacts

(1) Costs of Noise, Congestion and Crashes Associated With Additional (Rebound) Driving

Although it provides benefits to drivers as described above, increased vehicle use associated with the rebound effect also contributes to increased

traffic congestion, motor vehicle crashes, and highway noise. Depending on how the additional travel is distributed over the day and where it takes place, additional vehicle use can contribute to traffic congestion and delays by increasing the number of vehicles using facilities that are already heavily traveled. These added delays impose higher costs on drivers and other vehicle occupants in the form of increased travel time and operating expenses. At the same time, this additional travel also increases costs associated with traffic crashes and vehicle noise.

The agencies estimate these costs using the same methodology as used in the two light-duty and the HD Phase 1 rule analyses, which relies on estimates of congestion, crash, and noise costs imposed by automobiles and light trucks developed by the Federal Highway Administration to estimate these increased external costs caused by added driving.⁹⁰⁰ We provide the details behind the estimates in Chapter 8.7 of the RIA. Table IX–23 presents the estimated annual impacts associated with crash, congestion and noise along with net present values at both 3 percent and 7 percent discount rates. Table IX–24 presents the estimated discounted model year lifetime impacts associated with crashes, congestion and noise. The methodology used in this final rule is the same as that used in the proposal, except that costs were updated to 2013 dollars.

(2) Benefits Associated With Reduced Refueling Time

By reducing the frequency with which drivers typically refuel their vehicles and by extending the upper limit of the range that can be traveled before requiring refueling (*i.e.*, future fuel tank sizes remain constant), savings will be realized associated with less time spent refueling vehicles. Alternatively, refill intervals may remain the same (*i.e.*, future fuel tank sizes get smaller), resulting in the same number of refills as today but less time spent per refill

because there will be less fuel to refill. The agencies have estimated this impact using the former approach—by assuming that future tank sizes remain constant.

The savings in refueling time are calculated as the total amount of time the driver of a typical truck in each class will save each year as a consequence of pumping less fuel into the vehicle's tank. The calculation does not include any reduction in time spent searching for a fueling station or other time spent at the station; it is assumed that time savings occur only when truck operators are actually refueling their vehicles.

The calculation uses the reduced number of gallons consumed by truck type and divides that value by the tank volume and refill amount to get the number of refills, then multiplies that by the time per refill to determine the number of hours saved in a given year. The calculation then applies DOT-recommended values of travel time savings to convert the resulting time savings to their economic value, including a 1.2 percent growth rate in those time savings going forward.⁹⁰¹ The input metrics used in the analysis are presented in greater detail in RIA Chapter 9.7. The annual benefits associated with reduced refueling time are shown in Table IX–25 along with net present values at both 3 percent and 7 percent discount rates. The discounted model year lifetime benefits are shown in Table IX–26. The methodology used in this final rule is the same as that used in the proposal, except that costs have been updated to 2013 dollars.

(3) Benefits of Increased Travel Associated With Rebound Driving

The increase in travel associated with the rebound effect produces additional benefits to vehicle owners and operators, which reflect the value of the added (or more desirable) social and economic opportunities that become accessible with additional travel. The analysis estimates the economic benefits from increased rebound-effect driving as the sum of fuel expenditures incurred plus the consumer surplus from the additional accessibility it provides. As evidenced by the fact that vehicles make more frequent or longer trips when the cost of driving declines, the benefits from this added travel exceed added expenditures for the fuel consumed. The amount by which the benefits from this increased driving exceed its increased

fuel costs measures the net benefits from the additional travel, usually referred to as increased consumer surplus.

The agencies' analysis estimates the economic value of the increased consumer surplus provided by added driving using the conventional approximation, which is one half of the product of the decline in vehicle operating costs per vehicle-mile and the resulting increase in the annual number of miles driven. Because it depends on the extent of improvement in fuel economy, the value of benefits from increased vehicle use changes by model year and varies among alternative standards. Under even those alternatives that will impose the highest standards, however, the magnitude of the consumer surplus from additional vehicle use represents a small fraction of this benefit.

The annual benefits associated with increased travel are shown in Table IX-27 along with net present values at both 3 percent and 7 percent discount rates. The discounted model year lifetime benefits are shown in Table IX-28. The methodology used in this final rule is the same as that used in the proposal, except that costs have been updated to 2013 dollars.

K. Summary of Benefits and Costs

This section presents the costs, benefits, and other economic impacts of the Phase 2 standards. It is important to note that NHTSA's fuel consumption standards and EPA's GHG standards will both be in effect, and will jointly lead to increased fuel efficiency and reductions in GHG and non-GHG emissions. The individual categories of benefits and costs presented in the tables below are defined more fully and presented in more detail in Chapter 8 of the RIA. These include:

- The vehicle program costs (costs of complying with the vehicle CO₂ and fuel consumption standards),
- changes in fuel expenditures associated with reduced fuel use by more efficient vehicles and increased fuel use associated with the "rebound" effect, both of which result from the program,
 - the global economic value of reductions in GHGs,
 - the economic value of reductions in non-GHG pollutants,
 - costs associated with increases in noise, congestion, and crashes resulting from increased vehicle use,
 - savings in drivers' time from less frequent refueling,
 - benefits of increased vehicle use associated with the "rebound" effect, and
 - the economic value of improvements in U.S. energy security impacts.

For a discussion of the cost of ownership and the agencies' payback analysis of vehicles covered by this rule, please see Section IX.M.

The agencies conducted two analyses using two analytical methods referred to as Method A and Method B. For an explanation of these methods, please see Section I.D. And as discussed in Section X.A.1, the agencies present estimates of benefits and costs that are measured against two different assumptions about improvements in fuel efficiency that

might occur in the absence of the Phase 2 standards. The first case (Alternative 1a) uses a baseline that projects very little improvement in new vehicles in the absence of new Phase 2 standards, and the second (Alternative 1b) uses a more dynamic baseline that projects more significant improvements in vehicle fuel efficiency.

Table IX–29 shows benefits and costs for these standards from the perspective of a program designed to improve the nation's energy security and conserve

energy by improving fuel efficiency. From this viewpoint, technology costs occur when the vehicle is purchased. Fuel savings are counted as benefits that occur over the lifetimes of the vehicles produced during the model years subject to the Phase 2 standards as they consume less fuel. The table shows that benefits far outweigh the costs, and the final program is anticipated to result in large net benefits to the U.S economy.

TABLE IX–29—LIFETIME BENEFITS & COSTS OF THE FINAL PROGRAM FOR MODEL YEARS 2018–2029 VEHICLES USING ANALYSIS METHOD A

[Billions of 2013\$ discounted at 3% and 7%]

Category	Baseline 1a		Baseline 1b	
	3%	7%	3%	7%
Vehicle Program: Technology and Indirect Costs, Normal Profit on Additional Investments	24.4	16.6	23.7	16.1
Additional Routine Maintenance	1.7	0.9	1.7	0.9
Congestion, Crashes, Fatalities and Noise from Increased Vehicle Use ^a	3.2	1.9	3.1	1.8
Total Costs	29.3	19.4	28.5	18.8
Fuel Savings (valued at pre-tax prices)	163.0	87.0	149.1	79.7
Savings from Less Frequent Refueling	3.2	1.7	3.0	1.6
Economic Benefits from Additional Vehicle Use	5.5	3.5	5.4	3.4
Reduced Climate Damages from GHG Emissions ^b	36.0		33.0	
Reduced Health Damages from Non-GHG Emissions	30.0	16.1	27.1	14.6
Increased U.S. Energy Security	7.9	4.2	7.3	3.9
Total Benefits	246	149	225	136
Net Benefits	216	129	197	117

Notes:

^a“Congestion, Crashes, Fatalities and Noise from Increased Vehicle Use” includes NHTSA’s monetized value of estimated reductions in the incidence of highway fatalities associated with mass reduction in HD pickup and vans, but this does not include these reductions from tractor-trailers or vocational vehicles. This likely results in a conservative overestimate of these costs.

^bBenefits and net benefits use the 3 percent average global SC-CO₂, SC-CH₄, and SC-N₂O value applied to CO₂, CH₄, and N₂O emissions, respectively; GHG reductions also include HFC reductions, and include benefits to other nations as well as the U.S. See RIA Chapter 8.5 and Preamble Section IX.G for further discussion.

Table IX–30 through Table IX–32 report benefits and cost from the perspective of reducing GHG. Table IX–30 shows the annual impacts and net benefits of the final program for selected

future years, together with the net present values of cumulative annual impacts from 2018 through 2050, discounted at 3 percent and 7 percent rates.

Table IX–31 and Table IX–32 show the discounted lifetime costs and benefits for each model year affected by the Phase 2 standards at 3 percent and 7 percent discount rates, respectively.

Notes:

^a Positive values denote decreased social costs (benefits); negative values denote increased social costs. For an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

^b GHG benefit estimates include reductions in CO₂, CH₄, and N₂O but do not include the HFC reductions, as discussed in Section IX.G. Net present value of reduced GHG emissions is calculated differently than other benefits. The same discount rate used to discount the value of damages from future emissions (SC-CO₂, SC-CH₄, and SC-N₂O, each discounted at rates of 5, 3, 2.5 percent) is used to calculate net present value of SC-CO₂, SC-CH₄, and SC-N₂O, respectively, for internal consistency. Refer to the SC-CO₂ TSD for more detail.

^c Section IX.G notes that SC-GHG increases over time. For the years 2012–2050, the SC-CO₂ estimates range as follows: For Average SC-CO₂ at 5%: \$12–\$28; for Average SC-CO₂ at 3%: \$37–\$77; for Average SC-CO₂ at 2.5%: \$58–\$105; and for 95th percentile SC-CO₂ at 3%: \$105–\$237. For the years 2012–2050, the SC-CH₄ estimates range as follows: For Average SC-CH₄ at 5%: \$440–\$1,400; for Average SC-CH₄ at 3%: \$1,000–\$2,700; for Average SC-CH₄ at 2.5%: \$1,400–\$3,400; and for 95th percentile SC-CH₄ at 3%: \$2,800–\$7,400. For the years 2012–2050, the SC-N₂O estimates range as follows: For Average SC-N₂O at 5%: \$4,000–\$12,000; for Average SC-N₂O at 3%: \$14,000–\$30,000; for Average SC-N₂O at 2.5%: \$21,000–\$41,000; and for 95th percentile SC-N₂O at 3%: \$36,000–\$79,000. Section IX.G also presents these SC-GHG estimates.

Notes:

^a Positive values denote decreased social costs (benefits); negative values denote increased social costs. For an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the flat baseline, 1a, and dynamic baseline, 1b, please see Section X.A.1.

^b GHG benefit estimates include reductions in CO₂, CH₄, and N₂O but do not include the HFC reductions, as discussed in Section IX.G. Net present value of reduced GHG emissions is calculated differently than other benefits. The same discount rate used to discount the value of damages from future emissions (SC-CO₂, SC-CH₄, and SC-N₂O, each discounted at rates of 5, 3, 2.5 percent) is used to calculate net present value of SC-CO₂, SC-CH₄, and SC-N₂O, respectively, for internal consistency. Refer to the SC-CO₂ TSD for more detail.

^c Section IX.G notes that SC-GHG increases over time. For the years 2012–2050, the SC-CO₂ estimates range as follows: For Average SC-CO₂ at 5%: \$12–\$28; for Average SC-CO₂ at 3%: \$37–\$77; for Average SC-CO₂ at 2.5%: \$58–\$105; and for 95th percentile SC-CO₂ at 3%: \$105–\$237. For the years 2012–2050, the SC-CH₄ estimates range as follows: For Average SC-CH₄ at 5%: \$440–\$1,400; for Average SC-CH₄ at 3%: \$1,000–\$2,700; for Average SC-CH₄ at 2.5%: \$1,400–\$3,400; and for 95th percentile SC-CH₄ at 3%: \$2,800–\$7,400. For the years 2012–2050, the SC-N₂O estimates range as follows: For Average SC-N₂O at 5%: \$4,000–\$12,000; for Average SC-N₂O at 3%: \$14,000–\$30,000; for Average SC-N₂O at 2.5%: \$21,000–\$41,000; and for 95th percentile SC-N₂O at 3%: \$36,000–\$79,000. Section IX.G also presents these SC-GHG estimates.

L. Employment Impacts

Executive Order 13563 (January 18, 2011) directs federal agencies to consider regulatory impacts on, among other criteria, job creation.⁹⁰² According to the Executive Order “Our regulatory system must protect public health, welfare, safety, and our environment while promoting economic growth, innovation, competitiveness, and job creation. It must be based on the best available science.” Analysis of employment impacts of a regulation is not part of a standard benefit-cost analysis (except to the extent that labor costs contribute to costs). Employment impacts of federal rules are of general interest, however, and have been particularly so, historically, in the auto sector during periods of challenging labor market conditions. For this reason, we are describing the connections of these standards to employment in the regulated sector, the motor vehicle manufacturing sector, as well as the motor vehicle body and trailer and motor vehicle parts manufacturing sectors.⁹⁰³

The overall effect of the final rules on motor vehicle sector employment depends on the relative magnitude of output and substitution effects, described below. Because we do not have quantitative estimates of the output effect, and only a partial estimate of the substitution effect, we cannot reach a quantitative estimate of the overall employment effects of the final rules on motor vehicle sector employment or even whether the total effect will be positive or negative.

According to the U.S. Bureau of Labor Statistics, in 2015, about 910,000 people in the U.S. were employed in the Motor Vehicle and Parts Manufacturing Sector (NAICS 3361, 3362, and 3363),⁹⁰⁴ the

directly regulated sector. The employment effects of these final rules are expected to expand beyond the regulated sector. Though some of the parts used to achieve these standards are likely to be built by motor vehicle manufacturers (including trailer manufacturers) themselves, the motor vehicle parts manufacturing sector also plays a significant role in providing those parts, and will also be affected by changes in vehicle sales. Changes in truck sales, discussed in Section IX.F.(2), could also affect employment for truck and trailer vendors. As discussed in Section IX.C., this final rule is expected to reduce the amount of fuel these vehicles use, and thus affect the petroleum refinery and supply industries as well. Finally, since the net reduction in cost associated with these final rules is expected to lead to lower transportation and shipping costs, in a competitive market a substantial portion of those cost savings will be passed along to consumers, who then will have additional discretionary income (how much of the cost is passed along to consumers depends on market structure and the relative price elasticities). The final rules are not expected to have any notable inflationary or recessionary effect.

The employment effects of environmental regulation are difficult to disentangle from other economic changes and business decisions that affect employment, over time and across regions and industries. In light of these difficulties, we lean on economic theory to provide a constructive framework for approaching these assessments and for better understanding the inherent complexities in such assessments. Neoclassical microeconomic theory describes how profit-maximizing firms adjust their use of productive inputs in response to changes in their economic conditions.⁹⁰⁵ Berman and Bui (2001, pp. 274–75) model two components that drive changes in firm-level labor demand: Output effects and substitution

effects.⁹⁰⁶ Regulation can affect the profit-maximizing quantity of output by changing the marginal cost of production. If regulation causes marginal cost to increase, it will place upward pressure on output prices, leading to a decrease in the quantity demanded, and resulting in a decrease in production. The output effect describes how, holding labor intensity constant, a decrease in production causes a decrease in labor demand. As noted by Berman and Bui, although many assume that regulation increases marginal cost, it need not be the case. A regulation could induce a firm to upgrade to less polluting and more efficient equipment that lowers marginal production costs, or it may induce use of technologies that may prove popular with buyers or provide positive network externalities (see Section IX.A. for discussion of this effect). In such a case, output could increase.

The substitution effect describes how, holding output constant, regulation affects labor intensity of production. Although increased environmental regulation may increase use of pollution control equipment and energy to operate that equipment, the impact on labor demand is ambiguous. For example, equipment inspection requirements, specialized waste handling, or pollution technologies that alter the production process may affect the number of workers necessary to produce a unit of output. Berman and Bui (2001) model the substitution effect as the effect of regulation on pollution control equipment and expenditures required

⁹⁰⁵ See Layard, P.R.G., and A. A. Walters (1978), *Microeconomic Theory* (McGraw-Hill, Inc.), Chapter 9 (Docket ID EPA–HQ–OAR–2014–0827–0070), a standard microeconomic theory textbook treatment, for a discussion.

⁹⁰⁶ Berman, E. and L. T. M. Bui (2001). “Environmental Regulation and Labor Demand: Evidence from the South Coast Air Basin.” *Journal of Public Economics* 79(2): 265–295 (Docket EPA–HQ–OAR–2014–0827–0074). The authors also discuss a third component, the impact of regulation on factor prices, but conclude that this effect is unlikely to be important for large competitive factor markets, such as labor and capital. Morgenstern, Pizer and Shih (Morgenstern, Richard D., William A. Pizer, and Jih-Shyang Shih (2002). “Jobs versus the Environment: An Industry-Level Perspective.” *Journal of Environmental Economics and Management* 43: 412–436, Docket EPA–HQ–OAR–2014–0827–0088) use a similar model, but they break the employment effect into three parts: (1) A demand effect; (2) a cost effect; and (3) a factor-shift effect.

by the regulation and the corresponding change in labor intensity of production.

In summary, as output and substitution effects may be positive or negative, theory alone cannot predict the direction of the net effect of regulation on labor demand at the level of the regulated firm. Operating within the bounds of standard economic theory, empirical estimation of net employment effects on regulated firms is possible when data and methods of sufficient detail and quality are available. The literature, however, illustrates difficulties with empirical estimation. For example, studies sometimes rely on confidential plant-level employment data from the U.S. Census Bureau, possibly combined with pollution abatement expenditure data that are too dated to be reliably informative. In addition, the most commonly used empirical methods do not permit estimation of net effects.

The conceptual framework described thus far focused on regulatory effects on plant-level decisions within a regulated industry. Employment impacts at an individual plant do not necessarily represent impacts for the sector as a whole. The approach must be modified when applied at the industry level. At the industry level, labor demand is more responsive if: (1) The price elasticity of demand for the product is high, (2) other factors of production can be easily substituted for labor, (3) the supply of other factors is highly elastic, or (4) labor costs are a large share of total production costs.⁹⁰⁷ For example, if all firms in an industry are faced with the same regulatory compliance costs and product demand is inelastic, then industry output may not change much, and output of individual firms may change slightly.⁹⁰⁸ In this case, the output effect may be small, while the substitution effect depends on input substitutability. Suppose, for example, that new equipment for fuel efficiency improvements requires labor to install and operate. In this case, the substitution effect may be positive, and with a small output effect, the total effect may be positive. As with potential effects for an individual firm, theory cannot determine the sign or magnitude of industry-level regulatory effects on labor demand. Determining these signs

and magnitudes requires additional sector-specific empirical study. For environmental rules, much of the data needed for these empirical studies is not publicly available, would require significant time and resources in order to access confidential U.S. Census data for research, and also would not be necessary for other components of a typical RIA.

In addition to changes to labor demand in the regulated industry, net employment impacts encompass changes in other related sectors. For example, these standards are expected to increase demand for fuel-saving technologies. This increased demand may increase revenue and employment in the firms providing these technologies. At the same time, the regulated industry is purchasing the equipment, and these costs may impact labor demand at regulated firms. Therefore, it is important to consider the net effect of compliance actions on employment across multiple sectors or industries.

If the U.S. economy is at full employment, even a large-scale environmental regulation is unlikely to have a noticeable impact on aggregate net employment.⁹⁰⁹ Instead, labor would primarily be reallocated from one productive use to another, and net national employment effects from environmental regulation would be small and transitory (e.g., as workers move from one job to another).⁹¹⁰ The International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW) commented that, when the 900,000 workers in the auto sector are combined with “jobs from other sectors that are dependent on the industry,” the industry “is responsible for 7.25 million jobs nationwide, or about 3.8 percent of private-sector employment.” The agencies consider the 900,000 motor-vehicle-sector jobs to be in the industry directly affected by these standards; for the reasons discussed here, the overall state of the U.S. economy is likely to have a much more significant effect on the people employed in other sectors than these standards.

⁹⁰⁹ Full employment is a conceptual target for the economy where everyone who wants to work and is available to do so at prevailing wages is actively employed. The unemployment rate at full employment is not zero.

⁹¹⁰ Arrow et al. (1996). “Benefit-Cost Analysis in Environmental, Health, and Safety Regulation: A Statement of Principles.” American Enterprise Institute, the Annapolis Center, and Resources for the Future, Docket EPA-HQ-OAR-2014-0827-0073. See discussion on bottom of p. 6. In practice, distributional impacts on individual workers can be important, as discussed later in this section.

Affected sectors may experience transitory effects as workers change jobs. Some workers may retrain or relocate in anticipation of new requirements or require time to search for new jobs, while shortages in some sectors or regions could bid up wages to attract workers. These adjustment costs can lead to local labor disruptions. Although the net change in the national workforce is expected to be small, localized reductions in employment may adversely impact individuals and communities just as localized increases may have positive impacts.

If the economy is operating at less than full employment, economic theory does not clearly indicate the direction or magnitude of the net impact of environmental regulation on employment; it could cause either a short-run net increase or short-run net decrease.⁹¹¹ An important research question is how to accommodate unemployment as a structural feature in economic models. This feature may be important in assessing large-scale regulatory impacts on employment.⁹¹²

Environmental regulation may also affect labor supply. In particular, pollution and other environmental risks may impact labor productivity or employees’ ability to work.⁹¹³ While the theoretical framework for analyzing labor supply effects is analogous to that for labor demand, it is more difficult to study empirically. There is a small emerging literature described in the next section that uses detailed labor and environmental data to assess these impacts.

To summarize, economic theory provides a framework for analyzing the impacts of environmental regulation on employment. The net employment effect incorporates expected employment changes (both positive and negative) in the regulated sector and elsewhere. Labor demand impacts for regulated firms, and also for the regulated industry, can be decomposed into output and substitution effects which may be either negative or positive. Estimation of net employment effects for regulated sectors is possible when data of sufficient detail and quality are

⁹⁰⁸ This discussion draws from Berman, E. and L. T. M. Bui (2001). “Environmental Regulation and Labor Demand: Evidence from the South Coast Air Basin.” *Journal of Public Economics* 79(2): 265–295 (Docket EPA-HQ-OAR-2014-0827), p. 293, Docket EPA-HQ-OAR-2014-0827-0074.

available. Finally, economic theory suggests that labor supply effects are also possible. In the next section, we discuss the empirical literature.

Achates Power, the American Council for an Energy-Efficient Economy, BlueGreen Alliance, Ceres, Environmental Defense Fund (EDF), Natural Resources Defense Council, and JD Gilroy expressed support for the standards' potential to increase employment in the vehicle manufacturing industry. They argued that the standards will drive new jobs, reward organizations that innovate with respect to fuel efficiency, and help maintain the U.S. position as a leader in industries related to truck manufacturing and fuel efficiency technology. Brian Mannix points out the difficulty associated with generating complete employment forecasts that include all direct and indirect effects. He concludes that the agencies are correct to be careful about estimating a definitive forecast.

Comments from the International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW) urge EPA and NHTSA to ensure that the standards avoid market disruptions or "pre-buy/no-buy" boom and bust cycles. UAW suggests that in the past, market disruptions caused by pre-buy in anticipation of the 2007 and 2010 NO_x and PM standards contributed to the layoff of 10,000 UAW workers in 2009, though these layoffs were also partly driven by the Great Recession. As pointed out in the comments from EDF, fuel economy standards are fundamentally different from the past standards, because increases in costs for new technology are offset by fuel savings that accrue to the buyer. As a result these standards are less likely to cause disruptions to vehicle purchasing trends. Moreover, as discussed in Section IX.F.(2) above, there is no evidence to date that the HD GHG/fuel consumption rules have resulted in pre-buy/no-buys.

NAFA Fleet Management Association expressed concern that the standards would make it more difficult to hire qualified drivers and technicians, and would require additional employee training. As discussed in Section IX.A., the effects of the standards on hiring and retention of drivers and technicians are not well understood. The agencies expect that normal market forces should help to alleviate any labor shortages, whether or not they are associated with the standards. The Recreational Vehicle (RV) Industry Association expresses concern that buyers RVs do not consider fuel expenditures when purchasing vehicles; as a result, increased up-front

costs of the vehicle might reduce their sales. The RV industry was disproportionately hurt during the Great Recession and has only recently experienced a recovery.⁹¹⁴ However, one of the main drivers of the turnaround appears to be low gas prices,⁹¹⁶ which suggests that RV buyers may put some weight on fuel savings in their buying decisions; if so, the reduction in expected fuel costs may mitigate at least some of the effect of higher up-front prices.

(1) Current State of Knowledge Based on the Peer-Reviewed Literature

In the labor economics literature there is an extensive body of peer-reviewed empirical work analyzing various aspects of labor demand, relying on the above theoretical framework.⁹¹⁷ This work focuses primarily on the effects of employment policies, e.g. labor taxes, minimum wage, etc.⁹¹⁸ In contrast, the peer-reviewed empirical literature specifically estimating employment effects of environmental regulations is very limited. Several empirical studies⁹¹⁹ suggest that net employment

impacts may be zero or slightly positive but small even in the regulated sector. Other research suggests that more highly regulated counties may generate fewer jobs than less regulated ones.⁹²⁰ However, since these latter studies compare more regulated to less regulated counties, they overstate the net national impact of regulation to the extent that regulation causes plants to locate in one area of the country rather than another. List et al. (2003)⁹²¹ find some evidence that this type of geographic relocation may be occurring. Overall, the peer-reviewed literature does not contain evidence that environmental regulation has a large impact on net employment (either negative or positive) in the long run across the whole economy.

Analytic challenges make it very difficult to accurately produce net employment estimates for the whole economy that would appropriately capture the way in which costs, compliance spending, and environmental benefits propagate through the macro-economy. Quantitative estimates are further complicated by the fact that macroeconomic models often have very little sectoral detail and usually assume that the economy is at full employment. EPA is currently in the process of seeking input from an independent expert panel on modeling economy-wide impacts, including employment effects. For more information, see: <https://federalregister.gov/a/2014-02471>.

(2) Employment Impacts in the Motor Vehicle and Parts Manufacturing Sector

This section describes changes in employment in the motor vehicle, trailer, and parts (hence, motor vehicle) manufacturing sectors due to these final rules. We focus on the motor vehicle manufacturing sector because it is directly regulated, and because it is likely to bear a substantial share of

changes in employment due to these final rules. We include discussion of effects on the parts manufacturing sector, because the motor vehicle manufacturing sector can either produce parts internally or buy them from an external supplier, and we do not have estimates of the likely breakdown of effort between the two sectors.

We follow the theoretical structure of Berman and Bui⁹²² of the impacts of regulation in employment in the regulated sectors. In Berman and Bui's (2001, p. 274–75) theoretical model, as described above, the change in a firm's labor demand arising from a change in regulation is decomposed into two main components: Output and substitution effects.⁹²³ As the output and substitution effects may be both positive, both negative, or some combination, standard neoclassical theory alone does not point to a definitive net effect of regulation on labor demand at regulated firms.

Following the Berman and Bui framework for the impacts of regulation on employment in the regulated sector, we consider two effects for the motor vehicle sector: The output effect and the substitution effect.

(a) The Output Effect

If truck or trailer sales increase, then more people will be required to assemble trucks, trailers, and their components. If truck or trailer sales decrease, employment associated with these activities will decrease. The effects of this final rulemaking on HD vehicle sales thus depend on the perceived desirability of the new vehicles. On one hand, this final rulemaking will increase truck and trailer costs; by itself, this effect would reduce truck and trailer sales. In addition, while decreases in truck performance would also decrease sales, this program is not expected to have any negative effect on truck performance. On the other hand, this final rulemaking will reduce the fuel costs of operating

the trucks; by itself, this effect would increase truck sales, especially if potential buyers have an expectation of higher fuel prices. The agencies have not made an estimate of the potential change in truck or trailer sales. However, as discussed in IX.E., the agencies have estimated an increase in vehicle miles traveled (*i.e.*, VMT rebound) due to the reduced operating costs of trucks meeting these standards. Since increased VMT is most likely to be met with more drivers and more trucks, our projection of VMT rebound is suggestive of an increase in vehicle sales and truck driver employment (recognizing that these increases may be partially offset by a decrease in manufacturing and sales for equipment of other modes of transportation such as rail cars or barges).

(b) The Substitution Effect

The output effect, above, measures the effect due to new truck and trailer sales only. The substitution effect includes the impacts due to the changes in technologies needed for vehicles to meet these standards, separate from the effect on output (that is, as though holding output constant). This effect includes both changes in employment due to incorporation of abatement technologies and overall changes in the labor intensity of manufacturing. We present estimates for this effect to provide a sense of the order of magnitude of expected impacts on employment, which we expect to be small in the automotive sector, and to repeat that regulations may have positive as well as negative effects on employment.

One way to estimate this effect, given the cost estimates for complying with the final rule, is to use the ratio of workers to each \$1 million of expenditures in that sector. The use of these ratios has both advantages and limitations. It is often possible to estimate these ratios for quite specific sectors of the economy: For instance, it is possible to estimate the average number of workers in the motor vehicle body and trailer manufacturing sector per \$1 million spent in the sector, rather than use the ratio from another, more aggregated sector, such as motor vehicle manufacturing. As a result, it is not necessary to extrapolate employment ratios from possibly unrelated sectors. On the other hand, these estimates are averages for the sectors, covering all the activities in those sectors; they may not be representative of the labor required when expenditures are required on specific activities, or when manufacturing processes change sufficiently that labor intensity changes. For instance, the ratio for the motor

vehicle manufacturing sector represents the ratio for all vehicle manufacturing, not just for emissions reductions associated with compliance activities. In addition, these estimates do not include changes in sectors that supply these sectors, such as steel or electronics producers. They thus may best be viewed as the effects on employment in the motor vehicle sector due to the changes in expenditures in that sector, rather than as an assessment of all employment changes due to these changes in expenditures. In addition, this approach estimates the effects of increased expenditures while holding constant the labor intensity of manufacturing; it does not take into account changes in labor intensity due to changes in the nature of production. This latter effect could either increase or decrease the employment impacts estimated here.⁹²⁴

Some of the costs of these final rules will be spent directly in the motor vehicle manufacturing sector, but it is also likely that some of the costs will be spent in the motor vehicle body and trailer and motor vehicle parts manufacturing sectors. The analysis here draws on estimates of workers per \$1 million of expenditures for each of these sectors.

There are several public sources for estimates of employment per \$1 million expenditures. The U.S. Bureau of Labor Statistics (BLS) provides its Employment Requirements Matrix (ERM),⁹²⁵ which provides direct estimates of the employment per \$1 million in sales of goods in 202 sectors. The values considered here are for Motor Vehicle Manufacturing (NAICS 3361), Motor Vehicle Body and Trailer Manufacturing (NAICS 3362), and Motor Vehicle Parts Manufacturing (NAICS 3363) for 2014.

The Census Bureau provides the Annual Survey of Manufacturers⁹²⁶ (ASM), a subset of the Economic Census (EC), based on a sample of establishments; though the EC itself is more complete, it is conducted only every 5 years, while the ASM is annual. Both include more sectoral detail than the BLS ERM: For instance, while the ERM includes the Motor Vehicle

⁹²² Berman, E. and L. T. M. Bui (2001). "Environmental Regulation and Labor Demand: Evidence from the South Coast Air Basin." *Journal of Public Economics* 79(2): 265–295 (Docket EPA–HQ–OAR2014–0827–0074).

⁹²³ The authors also discuss a third component, the impact of regulation on factor prices, but conclude that this effect is unlikely to be important for large competitive factor markets, such as labor and capital. Morgenstern, Pizer and Shih (2002) use a similar model, but they break the employment effect into three parts: (1) The demand effect; (2) the cost effect; and (3) the factor-shift effect. See Morgenstern, Richard D., William A. Pizer, and Jhih-Shyang Shih. "Jobs Versus the Environment: An Industry-Level Perspective." *Journal of Environmental Economics and Management* 43 (2002): 412–436 (Docket EPA–HQ–OAR–2014–0827–00888).

⁹²⁴ As noted above, Morgenstern et al. (2002) separate the effect of holding output constant into two effects: The cost effect, which holds labor intensity constant, and the factor shift effect, which estimates those changes in labor intensity.

⁹²⁵ http://www.bls.gov/emp/ep_data_emp_requirements.htm; see "HD Substitution Effect Employment Impacts," Docket EPA–HQ–OAR–2014–0827.

⁹²⁶ <http://www.census.gov/manufacturing/asm/index.html>; see "HD Substitution Effect Employment Impacts," Docket EPA–HQ–OAR–2014–0827.

Manufacturing sector, the ASM and EC have detail at the 6-digit NAICS code level (e.g., light truck and utility vehicle manufacturing). While the ERM provides direct estimates of employees/\$1 million in expenditures, the ASM and EC separately provide number of employees and value of shipments; the direct employment estimates here are the ratio of those values. The values reported are for Motor Vehicle Manufacturing (NAICS 3361), Light Truck and Utility Vehicle Manufacturing (NAICS 336112), Heavy Duty Truck Manufacturing (NAICS 33612), Motor Vehicle Body and Trailer manufacturing (NAICS 3362), and Motor Vehicle Parts Manufacturing (NAICS 3363).

RIA Chapter 8.11.2.2 provides the details on the values of workers per \$1 million in expenditures in 2014 (2012 for EC) for the sectors mentioned above. In 2013\$, these range from 0.4 workers per \$1 million for Motor Vehicle Manufacturing in the ERM as well as for Light Truck & Utility Vehicle Manufacturing in the ASM, to 3.5 workers per \$1 million in expenditures for Motor Vehicle Body and Trailer Manufacturing in the EC. These values are then adjusted to remove the employment effects of imports through

use of a ratio of domestic production to domestic sales of 0.78.⁹²⁷

Over time, the amount of labor needed in the motor vehicle industry has changed: Automation and improved methods have led to significant productivity increases. The BLS ERM, for instance, provided estimates that, in 1997, 1.09 workers in the Motor Vehicle Manufacturing sector were needed per \$1 million, but only 0.39 workers by 2014 (in 2013\$).⁹²⁸ Because the ERM is available annually for 1997–2014, we used these data to estimate productivity improvements over time. We then used these productivity estimates to project the ERM through 2027, and to adjust the ASM values for 2014 and the EC values for 2012. RIA Chapter 8.11.2 provides detail on these calculations.

Finally, to simplify the presentation and give a range of estimates, we compared the projected employment among the 3 sectors for the ERM, EC, and ASM, and we provide only the maximum and minimum employment effects estimated across the ERM, EC, and ASM. We provide the range rather than a point estimate because of the inherent difficulties in estimating employment impacts; the range gives an estimate of the expected magnitude. The ERM estimates in the Motor Vehicle Manufacturing Sector are consistently

the minimum values. The ASM estimates in the Motor Vehicle Body and Trailer Manufacturing Sector are the maximum values for all years but 2027, when the ASM values for Motor Vehicle Parts Manufacturing provide the maximum values.

Section IX.B. of the Preamble discusses the vehicle cost estimates developed for these final rules. The final step in estimating employment impacts is to multiply costs (in \$ millions) by workers per \$1 million in costs, to estimate employment impacts in the regulated and parts manufacturing sectors. Increased costs of vehicles and parts will, by itself, and holding labor intensity constant, be expected to increase employment between 2018 and 2027 between zero and 4.5 thousand jobs each year.

While we estimate employment impacts, measured in job-years, beginning with program implementation, some of these employment gains may occur earlier as motor vehicle manufacturers and parts suppliers hire staff in anticipation of compliance with the standards. A job-year is a way to calculate the amount of work needed to complete a specific task. For example, a job-year is one year of work for one person.

TABLE IX–33—EMPLOYMENT EFFECTS DUE TO INCREASED COSTS OF VEHICLES AND PARTS (SUBSTITUTION EFFECT), IN JOB-YEARS

Year	Costs (millions of 2013\$)	Minimum employment due to substitution effect (ERM estimates, expenditures in the Motor Vehicles Mfg sector)	Maximum employment due to substitution effect (ASM estimates, expenditures in the Body and Trailer Mfg sector ^a)
2018	227	0	400
2019	215	0	400
2020	220	0	300
2021	2,270	300	3,100
2022	2,243	300	2,900
2023	2,485	300	2,900
2024	3,890	400	4,200
2025	4,146	400	4,100
2026	4,203	400	3,800
2027	5,219	500	4,500

Note:

^a For 2027, the maximum employment effects are associated with the ASM's Motor Vehicle Parts Manufacturing sector.

(c) Summary of Employment Effects in the Motor Vehicle Sector

The overall effect of these final rules on motor vehicle sector employment depends on the relative magnitude of the output effect and the substitution

effect. Because we do not have quantitative estimates of the output effect, and only a partial estimate of the substitution effect, we cannot reach a quantitative estimate of the overall employment effects of these final rules

on motor vehicle sector employment or even whether the total effect will be positive or negative.

These standards are not expected to provide incentives for manufacturers to shift employment between domestic and

⁹²⁷ To estimate the proportion of domestic production affected by the change in sales, we use data from Ward's Automotive Group for total truck production in the U.S. compared to total truck sales in the U.S. For the period 2006–2015, the proportion is 78 percent (HD Substitution Effect

Employment Impacts, Docket EPA–HQ–OAR–2014–0827), ranging from 68 percent (2009) to 83 percent (2012) over that time.

⁹²⁸ http://www.bls.gov/emp/ep_data_emp_requirements.htm; see “HD Substitution Effect Employment Impacts,” Docket EPA–HQ–OAR–

2014–0827. This analysis used data for sectors 80 (Motor Vehicle Manufacturing), 81 (Motor Vehicle Body and Trailer Manufacturing), and 82 (Motor Vehicle Parts Manufacturing) from “Chain-weighted (2009 dollars) real domestic employment requirements tables.”

foreign production. This is because these standards will apply to vehicles sold in the U.S. regardless of where they are produced. If foreign manufacturers already have increased expertise in satisfying the requirements of the standards, there may be some initial incentive for foreign production, but the opportunity for domestic manufacturers to sell in other markets might increase. To the extent that the requirements of these final rules might lead to installation and use of technologies that other countries may seek now or in the future, developing this capacity for domestic production now may provide some additional ability to serve those markets.

(3) Employment Impacts in Other Affected Sectors

(a) Transport and Shipping Sectors

Although not directly regulated by these final rules, employment effects in the transport and shipping sector are likely to result from these regulations. If the overall cost of shipping a ton of freight decreases because of increased fuel efficiency (taking into account the increase in upfront purchasing costs), in a perfectly competitive industry some of these costs savings, depending on the relative elasticities of supply and demand, will be passed along to customers. Consumer Federation of America expects reduced shipping costs to be passed along to customers. With lower prices, demand for shipping would lead to an increase in demand for truck shipping services (consistent with the VMT rebound effect analysis) and therefore an increase in employment in the truck shipping sector. In addition, if the relative cost of shipping freight via trucks becomes cheaper than shipping by other modes (e.g., rail or barge), then employment in the truck transport industry is likely to increase. If the trucking industry is more labor intensive than other modes, we would expect this effect to lead to an overall increase in employment in the transport and shipping sectors.^{929 930} Such a shift would, however, be at the expense of employment in the sectors that are losing business to trucking. The first effect—a gain due to lower shipping costs—is likely to lead to a net increase

in employment. The second effect, due to mode-shifting, may increase employment in trucking, but decrease employment in other shipping sectors (e.g., rail or barge), with the net effects dependent on the labor-intensity of the sectors and the volumes.

(b) Fuel Suppliers

In addition to the effects on the trucking industry and related truck parts sector, these final rules will result in reductions in fuel use that lower GHG emissions. Fuel saving, principally reductions in liquid fuels such as diesel and gasoline, will affect employment in the fuel suppliers industry sectors, principally the Petroleum Refinery sector.

Section IX.C. of this Preamble provides estimates of the effects of these standards on expected fuel consumption. While reduced fuel consumption represents savings for purchasers of fuel, it also represents a loss in value of output for the petroleum refinery industry, which will result in reduced sectoral employment. Because this sector is material-intensive, the employment effect is not expected to be large.⁹³¹

(c) Fuel Savings

As a result of this final rulemaking, it is anticipated that trucking firms will experience fuel savings. Fuel savings lower the costs of transportation goods and services. In a competitive market, some of the fuel savings that initially accrue to trucking firms are likely to be passed along as lower transportation costs that, in turn, could result in lower prices for final goods and services. Some commenters provide estimates of per-household fuel savings ranging from \$150 per year by 2030 (Clean Fuels Ohio, Edison Solar, a mass comment campaign sponsored by Pew Charitable Trusts, Quasar Energy Group), to \$400 in 2035 (Environmental Defense Fund); they view these savings as providing benefits to the wider economy. The National Ready Mixed Concrete Association emphasizes concerns about the costs that the standards will impose. Although the agencies do not endorse the particular values provided in the comments, we agree that the standards will provide net benefits to the U.S.; as shown in Section IX.K., the benefits exceed the costs by a wide margin. As noted above, the Consumer Federation of America expects consumers to recover these fuel savings via the costs

of goods and services relying on HD vehicles. The agencies note that some of the savings might also be retained by firms for investments or for distributions to firm owners. Again, how much accrues to customers versus firm owners will depend on the relative elasticities of supply and demand. Regardless, the savings will accrue to some segment of consumers: Either owners of trucking firms or the general public, and the effect will be increased spending by consumers in other sectors of the economy, creating jobs in a diverse set of sectors, including retail and service industries.

As described in Section IX.C.(2), the retail value of fuel savings from this final rulemaking is projected to be \$15.8 billion (2013\$) in 2027, according to Table IX-6. If all those savings are spent, the fuel savings will stimulate increased employment in the economy through those expenditures. If the fuel savings accrue primarily to firm owners, they may either reinvest the money or take it as profit. Reinvesting the money in firm operations could increase employment directly. If they take the money as profit, to the extent that these owners are wealthier than the general public, they may spend less of the savings, and the resulting employment impacts would be smaller than if the savings went to the public. Thus, while fuel savings are expected to decrease employment in the refinery sector, they are expected to increase employment through increased consumer expenditures.

(4) Summary of Employment Impacts

The primary employment effects of these rules are expected to be found throughout several key sectors: Truck and engine manufacturers, the trucking industry, truck parts manufacturing, fuel production, and consumers. These rules initially takes effect in model year 2018; the unemployment rate at that time is unknowable. In an economy with full employment, the primary employment effect of a rulemaking is likely to be to move employment from one sector to another, rather than to increase or decrease employment. For that reason, we focus our partial quantitative analysis on employment in the regulated sector, to examine the impacts on that sector directly. We discuss the likely direction of other impacts in the regulated sector as well as in other directly related sectors, but we do not quantify those impacts, because they are more difficult to quantify with reasonable accuracy, particularly so far into the future.

For the regulated sector, we have not quantified the output effect. The

⁹³⁰ Association of American Railroads, "All Inclusive Index and Rail Adjustment Factor." June 3, 2011. See <http://www.aar.org/-/media/aar/RailCostIndexes/AAR-RCAF-2011-Q3.ashx>, Docket EPA-HQ-OAR-2014-0827-0065.

⁹³¹ In the 2014 BLS ERM cited above, the Petroleum and Coal Products Manufacturing sector has a ratio of workers per \$1 million of 0.215, lower than all but two of the 181 sectors with non-zero employment per \$1 million.

substitution effect is associated with potential increased employment between zero and 4.5 thousand jobs per year between 2018 and 2027, depending on the share of employment impacts in the affected sectors (Motor Vehicle Manufacturing, Motor Vehicle Body and Trailer Manufacturing, and Motor Vehicle Parts Manufacturing). These estimates do not include potential changes, either greater or less, in labor intensity of production. As mentioned above, some of these job gains may occur earlier as auto manufacturers and parts suppliers hire staff to prepare to comply with the standard.

Lower prices for shipping are expected to lead to an increase in demand for truck shipping services and, therefore, an increase in employment in that sector, though this effect may be offset somewhat by changes in employment in other shipping sectors. Reduced fuel production implies less employment in the fuel provision sectors. Finally, any net cost savings are expected to be passed along to some segment of consumers: Either the general public or the owners of trucking firms, who are expected then to increase employment through their expenditures. Under conditions of full employment, any changes in employment levels in

the regulated sector due to this program are mostly expected to be offset by changes in employment in other sectors.

M. Cost of Ownership and Payback Analysis

This section examines the economic impacts of the Phase 2 standards from the perspective of buyers, operators, and subsequent owners of new HD vehicles at the level of individual purchasers of different types of vehicles. In each case, the analysis assumes that HD vehicle manufacturers are able to recover their costs for improving fuel efficiency—including direct technology outlays, indirect costs, and normal profits on any additional capital investments—by charging higher prices to HD vehicle buyers.

Table IX–34 reports aggregate benefits and costs to buyers and operators of new HD vehicles for the final program using Method A. The table reports economic impacts on buyers using only the 7 percent discount rate, since that rate is intended to represent the opportunity cost of capital that HD vehicle buyers and users must divert from other investment opportunities to purchase more costly vehicles. As it shows, fuel savings and the other benefits from increased fuel efficiency—savings from less frequent refueling and

benefits from additional truck use—far outweigh the higher costs to buyers of new HD vehicles. As a consequence, buyers, operators, and subsequent owners of HD vehicles subject to the Phase 2 standards are together projected to experience large economic gains under the final program. It should be noted that, because the original buyers may not hold the vehicles for their lifetimes, and because those who own or operate the vehicles may not pay for the fuel, these benefits and costs do not necessarily represent benefits and costs to identifiable individuals.

As Table IX–34 shows, the agencies have estimated the increased costs for maintenance of the new technologies that HD vehicle manufacturers will employ to decrease fuel consumption, and these costs are included together with those for purchasing more fuel-efficient vehicles. Manufacturers' efforts to comply with the Phase 2 standards could also result in changes to vehicle performance and capacity for certain vehicles. For example, reducing the mass of HD vehicles in order to improve fuel efficiency could be used to improve their load-carrying capabilities, while some engine technologies and aerodynamic modifications could reduce payload capacity.

TABLE IX–34—MY 2018–2029 LIFETIME AGGREGATE IMPACTS OF THE FINAL PROGRAM ON ALL HD VEHICLE BUYERS AND OPERATORS USING METHOD A
(Billions of 2013\$, Discounted at 7%)^a

	Baseline 1a	Baseline 1b
Vehicle costs	16.6	16.1
Maintenance costs	0.9	0.9
Total costs to HD vehicle buyers	17.5	17.0
Fuel savings ^b (valued at retail prices)	97.7	89.5
Refueling benefits	1.7	1.6
Increased travel benefits	3.5	3.4
Total benefits to HD vehicle buyers/operators	103	94.5
Net benefits to HD vehicle buyers/operators^c	85.4	77.5

Notes:

^aFor an explanation of analytical Methods A and B, please see Section I.D; for an explanation of the less dynamic baseline, 1a, and more dynamic baseline, 1b, please see Section X.A.1.

^bFuel savings includes fuel consumed during additional rebound driving.

^cNet benefits shown do not include benefits associated with carbon or other co-pollutant emission reductions, crash/congestion/noise impacts, energy security, etc.

It is also useful to examine the cost of purchasing and owning a new vehicle that complies with the Phase 2 standards and its payback period—the point at which cumulative savings from lower fuel expenditures outpace increased vehicle costs. For example, a new MY 2027 tractor is estimated to cost roughly \$13,550 more (on average, or roughly 13 to 14 percent of a typical \$100,000 reference case tractor) due to

the addition of new GHG reducing/fuel consumption improving technology. This new technology will result in lower fuel consumption and, therefore, reduced fuel expenditures. But how many months or years will pass before the reduced fuel expenditures will surpass the increased upfront costs?

Table IX–35 presents the discounted annual increased vehicle costs and fuel savings associated with owning a new MY 2027 HD pickup or van using both

3 percent and 7 percent discount rates. Table IX–36 and Table IX–37 show the same information for a MY 2027 vocational vehicle and a tractor/trailer, respectively. These comparisons include sales taxes, excise taxes (for vocational and tractor/trailer) and increased insurance expenditures on the higher value vehicles, as well as maintenance costs throughout the lifetimes of affected vehicles.

The fuel expenditure column uses retail fuel prices specific to gasoline and diesel fuel as projected in AEO2015.⁹³² This payback analysis does not include other impacts, such as reduced refueling events, the value of driving potential rebound miles, or noise, congestion and crashes. We use retail fuel prices and

exclude these other private and social impacts because the analysis is intended to focus on those factors that are most important to buyers when considering a new vehicle purchase, and to include only those factors that have clear dollar impacts on HD vehicle buyers.

As shown, payback will occur in the 3rd year of ownership for HD pickups

and vans (the first year where cumulative net costs turn negative), in the 4th year for vocational vehicles and early in the 2nd year for tractor/trailers. Note that each table reflects the average vehicle and reflects proper weighting of fuel consumption/costs (gasoline vs. diesel).

*N. Safety Impacts**(1) Summary of Supporting HD Vehicle Safety Research*

As discussed in the Notice of Proposed Rulemaking, NHTSA and EPA considered the potential safety impact of technologies that improve Medium- and Heavy-Duty vehicle fuel efficiency and GHG emissions when determining potential regulatory alternatives. The safety assessment of the technologies in this rule was informed by two comprehensive NAS reports, an extensive analysis of safety effects of HD pickups and vans using estimates from the DOT report on the effect of mass reduction and vehicle size on safety, and focused agency-sponsored safety testing and research. The following section provides a concise summary of the literature and work considered by the agencies in development of this final rule.

(a) National Academy of Sciences Medium and Heavy Duty Phase 1 and Phase 2 Reports

As required by EISA, the National Research Council has been conducting continuing studies of the technologies and approaches for reducing the fuel consumption of medium- and heavy-duty vehicles. The first was a report issued in 2010, “Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles” (“NAS Report”). The second was a report issued in 2014, “Reducing the Fuel Consumption and Greenhouse Gas Emissions of Medium- and Heavy-Duty Vehicles, Phase Two-First Report” (“NAS HD Phase 2 First Report”). While the reports primarily focused on reducing vehicle fuel consumption and emissions through technology application, and examined potential regulatory frameworks, both

reports contain findings and recommendations related to safety. In developing this rule, the agencies carefully considered the reports’ findings related to safety.

In particular, NAS indicated that idle reduction strategies can also accommodate for the safety of the driver in both hot and cold weather conditions. The agencies considered this potential approach for application of idle reduction technologies by allowing for override provisions, as defined in 40 CFR 1037.660(b), where operator safety is a primary consideration. Override is allowed if the external ambient temperature reaches a level below which or above which the cabin temperature cannot be maintained within reasonable heat or cold exposure threshold limit values for the health and safety of the operator (not merely comfort).

NAS also reported extensively on the emergence of natural gas (NG) as a viable fuel option for commercial vehicles, but alluded to the existence of uncertainties regarding its safety. The committee found that while the public crash databases do not contain information on vehicle fuel type, the information, at the time of the report, indicates that the crash-related safety risk for NG storage on vehicles does not appear to be appreciably different from diesel fuel risks. The committee also found that while there are two existing SAE-recommended practice standards for NG-powered HD vehicles, the industry could benefit from best practice directives to minimize crash risks for NG fuel tanks, such as on shielding to prevent punctures during crashes. As a final point, NAS stated that manufacturers and operators have a great incentive to prevent possible NG leakage from a vehicle fuel system because it will be a significant safety

concern and reduce vehicle range. No recommendations were made for additional Federal safety regulations for these vehicles. In response, the agencies reviewed and discussed the existing NG vehicle standards and best practices cited by NAS in Section XI of the NPRM.

In the NAS Committee’s Phase 1 report, the Committee indicated that aerodynamic fairings detaching from trucks on the road could be a potential safety issue. However, the Phase 2 interim report stated that “Anecdotal information gained during the observations of on-road trailers indicates a few skirts badly damaged or missing from one side. The skirt manufacturers report no safety concerns (such as side skirts falling off) and little maintenance needed.”

The NAS report also identified the link between tire inflation and condition and vehicle stopping distance and handling, which impacts overall safety. The committee found that tire pressure monitoring systems and automatic tire inflation systems are being adopted by fleets at an increasing rate. However, the committee noted that there are no standards for performance, display, and system validation. The committee recommended that NHTSA issue a white paper on the minimum performance of tire pressure systems from a safety perspective.

The agencies considered the safety findings in both NAS reports in developing this rule and conducted additional research on safety to further examine information and findings of the reports.

(b) DOT CAFE Model Heavy-Duty Pickup and Van Safety Analysis

This analysis considered the potential crash safety effects on the technologies manufacturers may apply to HD pickups

and vans to meet each of the regulatory alternatives evaluated in the NPRM. NHTSA research has shown that vehicle mass reduction affects overall societal fatalities associated with crashes and, most relevant to this rule, that mass reduction in heavier light- and medium-duty vehicles has an overall beneficial effect on societal fatalities. Reducing the mass of a heavier vehicle involved in a multiple vehicle crash reduces the likelihood of fatalities among the occupants of the other vehicle(s). In addition to the effects of mass reduction, the analysis anticipates that these standards, by reducing the cost of driving HD pickups and vans, will lead to increased travel by these vehicles and, therefore, more crashes involving these vehicles. Both the Method A and B analyses, both of which are included in the NPRM and are part of this final rulemaking, consider overall impacts from both of these factors, using a methodology similar to NHTSA's analyses for the MYs 2017–2025 CAFE and GHG emission standards.

The Method A analysis included estimates of the extent to which HD pickups and vans produced during MYs 2014–2030 may be involved in fatal crashes, considering the mass, survival, and mileage accumulation of these vehicles, taking into account changes in mass and mileage accumulation under each regulatory alternative. These calculations make use of the same coefficients applied to light trucks in the MYs 2017–2025 CAFE rulemaking analysis. As discussed above, vehicle miles traveled may increase due to the fuel economy rebound effect, resulting from improvements in vehicle fuel efficiency and cost of fuel, as well as the assumed future growth in average vehicle use. Increases in total lifetime mileage increase exposure to vehicle crashes, including those that result in fatalities. Consequently, the modeling system computes total fatalities attributed to vehicle use for vehicles of a given model year based on safety class and weight threshold. These calculations also include a term that accounts for the fact that some of the vehicles involved in future crashes will comply with more stringent safety standards than those involved in past crashes upon which the base rates of involvement in fatal crashes were estimated. Since the use of mass reducing technology is present within the model, safety impacts may also be observed whenever a vehicle's base weight decreases. Thus, in addition to computing total fatalities related to vehicle use, the modeling system also

estimates changes in fatalities due to reduction in a vehicle's curb weight.

The total fatalities attributed to vehicle use and vehicle weight change for vehicles of a given model year are then summed. Lastly, total fatalities occurring within the industry in a given model year are accumulated across all vehicles. In addition to using inputs to estimate the future involvement of modeled vehicles in crashes involving fatalities, the model also applies inputs defining other crash-related externalities estimated on a dollar per mile basis. For vehicles above 4,594 lbs—*i.e.*, the majority of the HD pickup and van fleet—mass reduction is estimated to reduce the net incidence of highway fatalities by 0.34 percent per 100 lbs of removed curb weight. For the few HD pickups and vans below 4,594 lbs, mass reduction is estimated to increase the net incidence of highway fatalities by 0.52 percent per 100 lbs. The overall effect of mass reduction in the segment is estimated to reduce the incidence of highway fatalities as there are more HD pickups and vans above 4,594 lbs than below. The projected increase in vehicle miles traveled, due to the fuel economy rebound effect, also potentially increases exposure to vehicle crashes and offsets these reductions.

(c) Volpe Research on MD/HD Fuel Efficiency Technologies

The 2010 National Research Council report “Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles” recommended that NHTSA perform a thorough safety analysis to identify and evaluate potential safety issues with fuel efficiency-improving technologies. The Department of Transportation Volpe Center's 2015 report titled “Review and Analysis of Potential Safety Impacts and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles” summarizes research and analysis findings on potential safety issues associated with both the diverse alternative fuels (natural gas-CNG and LNG, propane, biodiesel, and power train electrification), and the specific FE technologies recently adopted by the MD/HDV fleets.⁹³³ These include Intelligent Transportation Systems (ITS) and telematics, speed limiters, idle reduction devices, tire technologies (single-wide tires, and tire pressure

monitoring systems-TPMS and Automated Tire Inflation Systems-ATIS), aerodynamic components, vehicle light-weighting materials, and Long Combination Vehicles (LCVs).

Chapter 1 provides an overview of the study's rationale, background, and key objective, namely, to identify the technical and operational/behavioral safety benefits and disbenefits of MD/HDVs equipped with FE technologies and using emerging alternative fuels (AFs). Recent MD/HDV national fleet crash safety statistical averages are also provided for context, although no information exists in crash reports relating to specific vehicle FE technologies and fuels. (NHTSA/FARS and FMCSA/CSA databases do not include detailed information on vehicle fuel economy technologies, since the state crash report forms are not coded down to an individual fuel economy technology level).

Chapters 2 and 3 are organized by clusters of functionally-related FE technologies for vehicles and trailers (*e.g.*, tire systems, ITS, light-weighting materials, and aerodynamic systems) and alternative fuels, which are described and their respective associated potential safety issues are discussed. Chapter 2 summarizes the findings from a comprehensive review of available technical and trade literature and Internet sources regarding the benefits, potential safety hazards, and the applicable safety regulations and standards for deployed FE technologies and alternative fuels. Chapter 2 safety-relevant fuel-specific findings include:

- Both CNG- and LNG-powered vehicles present potential hazards, and call for well-known engineering and process controls to assure safe operability and crashworthiness. However, based on the reported incident rates of NGVs and the experiences of adopting fleets, it appears that NGVs can be operated at least as safely as diesel MD/HDVs.

- There are no safety contraindications to the large scale fleet adoption of CNG or LNG fueled heavy duty trucks and buses, and there is ample experience with the safe operation of large public transit fleets. Voluntary industry standards and best practices suffice for safety assurance, though improved training of CMV operators and maintenance staff in natural gas safety of equipment and operating procedures is needed.

- Observing CNG and LNG fuel system and maintenance facility standards, coupled with sound design, manufacture, and inspection of natural gas storage tanks will further reduce the

⁹³³ Brecher, A., Epstein, A. K., & Breck, A. (2015, June). *Review and analysis of potential safety impacts of and regulatory barriers to fuel efficiency technologies and alternative fuels in medium- and heavy-duty vehicles*. (Report No. DOT HS 812 159). Washington, DC: National Highway Traffic Safety Administration.

potential for leaks, tank ruptures, fires, and explosions.

- Biodiesel blends used as drop-in fuels have presented some operational safety concerns dependent on blending fraction, such as material compatibility, bio-fouling sludge accumulation, or cold-weather gelling. However, best practices for biodiesel storage, and improved gaskets and seals that are biodiesel resistant, combined with regular maintenance and leak inspection schedules for the fuel lines and components enable the safe use of biodiesel in newer MD/HDVs.

- Propane (LPG, or autogas) presents well-known hazards including ignition (due to leaks or crash) that are preventable by using Overfill Prevention Devices (OPDs), which supplement the automatic stop-fill system on the fueling station side, and pressure release devices (PRDs). Established best practices and safety codes (e.g., NFPA) have proven that propane fueled MD/HDVs can be as operationally safe as the conventionally-fueled counterparts.

- As the market penetration of hybrid and electric drivetrain accelerates, and as the capacity and reliability of lithium ion batteries used in Rechargeable Energy Storage Systems (RESS) improve, associated potential safety hazards (e.g., electrocution from stranded energy, thermal runaway leading to battery fire) have become well understood, preventable, and manageable. Existing and emerging industry technical and safety voluntary standards, applicable NHTSA regulations and guidance, and the growing experience with the operation of hybrid and electric MD/HDVs will enable the safe operation and large-scale adoption of safer and more efficient power-train electrification technologies.

The safety findings from literature review pertaining to the specific FE technologies implemented to date in the MD/HDV fleet include:

- Telematics—integrating on-board sensors, video, and audio alerts for MD/HDV drivers—offer potential improvements in both driver safety performance and fuel efficiency. Both camera and non-camera based telematics setups are currently integrated with available crash avoidance systems (such as ESC, RSC, LDWS, etc.) and appear to be well accepted by MD/HDV fleet drivers.

- Both experience abroad and the cited US studies of trucks equipped with active speed limiters indicated a safety benefit, as measured by up to 50 percent reduced crash rates, in addition to fuel savings and other benefits, with good CMV driver acceptance. Any negative aspects were small and

avoidable if all the speed limitation devices were set to the same speed, so there will be less need for overtaking at highway speeds.

- No literature reports of adverse safety impacts were found regarding implementation of on-board idle-reduction technologies in MD/HDVs (such as automatic start-stop, direct-fired heaters, and APUs).

- There was no clear consensus from the literature regarding the relative crash rates and highway safety impacts of LCVs, due to lack of sufficient data and controls and inconsistent study methodologies. Recent safety evaluations of LCVs and ongoing MAP-21 mandated studies will clarify and quantify this issue.

- Tire technologies for FE (including ATIS, TPMS, LRR and single-wide tires) literature raised potential safety concerns regarding lower stability or loss of control, e.g., when tire pressure is uneven or a single wide tire blows out on the highway. However, systems such as automated tire monitoring systems and stability enhancing electronic systems (ABS, ESC, and RSC) may compensate and mitigate any adverse safety impacts.

- Aerodynamic technologies that offer significant fuel savings have raised potential concerns about vehicle damage or injury in case of detached fairings or skirts, although there were no documented incidents of this type in the literature.

- Some light weighting materials may pose some fire safety and crashworthiness hazards, depending on their performance in structural or other vehicle subsystem applications (chassis, powertrain, and crash box or safety cage). Some composites (fiberglass, plastics, CFRP, foams) may become brittle on impact or due to weathering from UV exposure or extreme cold. Industry has developed advanced, high performance lightweight material options tailored to their automotive applications, e.g., thermoplastics resistant to UV and weathering. No examples of such lightweight material failures on MD/HDVs were identified in the literature.

Chapter 3 provides complementary inputs on the potential safety issues associated with FE technologies and alternative fuels obtained from Subject Matter Experts (SMEs). The broad cross-section of SMEs consulted had experience with the operation of “green” truck and bus fleets, were Federal program managers, or were industry developers of FE systems for MD/HDVs. Safety concerns raised by the SMEs can be prevented or mitigated by complying with applicable regulations

and safety standards and best practices, and are being addressed by evolving technologies, such as electronic collision prevention devices. Although SMEs raised some safety concerns, their experience indicates that system- or fuel-specific hazards can be prevented or mitigated by observing applicable industry standards, and by training managers, operators and maintenance staff in safety best practices. Specific safety concerns raised by SMEs based on their experience included:

- Alternative fuels did not raise major safety concerns, but generally required better education and training of staff and operators. There was a concern expressed regarding high pressure (4000 psi) CNG cylinders that could potentially explode in a crash scenario or if otherwise ruptured. However, aging CNG fuel tank safety can be assured by enforcing regulations such as FMVSS No. 304, and by periodic inspection and end-of-life disposal and replacement. A propane truck fleet manager stated that the fuel was as safe as or safer than gasoline, and reported no safety issues with the company’s propane, nor with hybrid gasoline-electric trucks. OEMs of drivetrain hybridization and electrification systems, including advanced Lithium Ion batteries for RESS, indicated that they undergo multiple safety tests and are designed with fail-safes for various misuse and abuse scenarios. Integration of hybrid components downstream by bodybuilders in retrofits, as opposed to new vehicles, was deemed a potential safety risk. Another potential safety concern raised was the uncertain battery lifetime due to variability of climate, duty-cycles, and aging. Without state-of-charge indicators, this could conceivably leave vehicles underpowered or stranded if the battery degrades and is not serviced or replaced in a timely manner.

- ITS and telematics raised no safety concerns; on the contrary, fleet managers stated that “efficient drivers are safer drivers.” Monitoring and recording of driver behavior, combined with coaching, appeared to reduce distracted and aggressive driving and provided significant FE and safety benefits.

- A wide-base single tire safety concern was the decrease in tire redundancy in case of a tire blowout at highway speeds. For LRRs, a concern was that they could negatively affect truck stopping distance and stability control.

- A speed-limiter safety concern was related to scenarios when such trucks pass other vehicles on the highway instead of staying in the right-hand lane

behind other vehicles. By combining speed limiters with driver training programs, overall truck safety could actually improve, as shown by international practice.

- Aerodynamic systems' safety performance to date was satisfactory, with no instances of on-road detaching. However, covering underside or other components with aerodynamic fairings can make them harder to inspect, such as worn lugs, CNG relief valve shrouds, wheel covers, and certain fairings. Drivers and inspectors need to be able to see through wheel covers and to be able to access lug nuts through them. These covers must also be durable to withstand frequent road abuse.

- For lightweighting materials, the safety concern raised was lower crashworthiness (debonding or brittle fracture on impact) and the potential for decreased survivability in vehicle fires depending on the specific material choice and its application.

The key finding from the literature review and SME interviews is that there appear to be no major safety hazards preventing the adoption of FE technologies, or the increased use of alternative fuels and vehicle electrification. In view of the scarcity of hard data currently available on actual highway crashes that can be directly or causally attributed to adoption of FE technologies and/or alternative fuels by MD/HDVs, and the limited experience with commercial truck and transit bus fleets operations equipped with these technologies, it was not possible to perform a quantitative, probabilistic risk assessment, or even a semi-quantitative preliminary hazard analysis (PHA). Chapter 4 employs a deterministic scenario-based hazard analysis of potential crash or other safety concerns identified from the literature review or raised by subject matter experts (SMEs) interviewed (e.g., interfaces with charging or refueling infrastructure). For each specific hazard scenario discussed, the recommended prevention or mitigation options, including compliance with applicable NHTSA or FMCSA regulations, and voluntary industry standards and best practices are identified, along with FE technology or fuel-specific operator training. SMEs safety concerns identified in Sec 3.3 were complemented with actual incidents, and developed into the hazard scenarios analyzed in Chapter 4.

The scenario-based deterministic hazard analysis reflected not only the literature findings and SMEs' safety concerns, but also real truck or bus mishaps that have occurred in the past. Key hazard analysis scenarios included: CNG-fueled truck and bus vehicle fires

or explosions due to tank rupture, when pressurized fuel tanks were degraded due to aging or when PRDs failed; LNG truck crashes leading to fires, or LNG refueling-related mishaps; the flammability or brittle fracture issues related to light weighting materials in crashes; reduced safety performance for either LRR or wide-base tires; highway pile-ups when LCVs attempt to pass at highway speeds; aerodynamic components detaching while the vehicle traveled on a busy highway or urban roadway; and fires resulting in overheated lithium ion batteries in electric or hybrid buses. These hypothetical worst case scenarios appear to be preventable or able to be mitigated by observing safety regulations and voluntary standards, or with engineering and operational best practices.

Chapter 5 reviews and discusses the existing federal and state regulatory framework for safely operating MD/HDVs equipped with FE technologies or powered by alternative fuels. The review identifies potential regulatory barriers to their large-scale deployment in the national fleet that could delay achievement of desired fuel consumption and environmental benefits, while ensuring equal or better safety performance.

Chapter 6 summarizes the major findings and recommendations of this preliminary safety analysis of fuel efficiency technologies and alternative fuels adopted by MD/HDVs. The scenario-based hazard analysis, based on the literature review and experts' inputs, indicates that MD/HDVs equipped with advanced FE technologies and/or using alternative fuels have manageable potentially adverse safety impacts. The findings suggest that the potential safety hazards identified during operation, maintenance, and crash scenarios can be prevented or mitigated by complying with safety regulations and voluntary standards and industry best practices. The study also did not identify any major regulatory barriers to rapid adoption of FE technologies and alternative fuels by the MD/HDV fleet.

(d) Oak Ridge National Laboratory (ORNL) Research on Low Rolling Resistance Truck Tires

DOT's Federal Motor Carrier Safety Administration and NHTSA sponsored a test program conducted by Oak Ridge National Laboratory to explore the effects of tire rolling resistance levels on Class 8 tractor-trailer stopping distance performance over a range of loading and surface conditions. The objective was to determine whether a relationship exists

between tire rolling resistance and stopping distance for vehicles of this type. The overall results of this research suggest that tire rolling resistance is not a reliable indicator of Class 8 tractor-trailer stopping distance.

The correlation coefficients (R2 values) for linear regressions of wet and dry stopping distance versus overall vehicle rolling resistance values did not meet the minimum threshold for statistical significance for any of the test conditions. Correlation between CRR and stopping distance was found to be negligible for the dry tests for both loading conditions. While correlation was higher for the wet testing (showing a slight trend in which lower CRRs correspond to longer stopping distances), it still did not meet the minimum threshold for statistical significance. In terms of compliance with Federal safety standards, it was found that the stopping distance performance of the vehicle with the four tire sets studied in this research (with estimated tractor CRRs which varied by 33 percent), were well under the FMVSS No. 121 stopping distance requirements.

(e) Additional Safety Considerations

The agencies considered the Organic Rankine Cycle waste heat recovery (WHR) as a fuel saving technology in the rulemaking timeframe. The basic approach of these systems is to use engine waste heat from multiple sources to evaporate a working fluid through a heat exchanger, which is then passed through a turbine or equivalent expander to create mechanical or electrical power. The working fluid is then condensed as it passes through a heat exchanger and returns to back to the fluid tank, and pulled back to the flow circuit through a pump to continue the cycle.

Despite the promising performance of pre-prototype WHR systems, manufacturers have not yet arrived at a consensus on which working fluid(s) to be used in WHR systems to balance concerns regarding performance, global warming potential (GWP), and safety. Working fluids have a high GWP (conventional refrigerant), are expensive (low GWP refrigerant), are hazardous (such as ammonia, etc.), are flammable (ethanol/methanol), or can freeze (water). One challenge is determining how to seal the working fluid properly under the vacuum condition and high temperatures to avoid safety issues for flammable/hazardous working fluids. Because of these challenges, choosing a working fluid will be an important factor for system safety, efficiency, and overall production viability.

The agencies believe manufacturers will require additional time and development effort to assure that a working fluid that is both appropriate, given the noted challenges, and has a low GWP for use in waste heat recovery systems. Based on this and other factors, the analysis used for both the proposed Preferred Alternative and for this final rule assumes that WHR will not achieve a significant market penetration for diesel tractor engines (*i.e.*, greater than 5 percent) until 2027, which will provide time for these considerations to be addressed. The agencies assume no use of this technology in the HD pickups and vans and vocational vehicle segments.

(2) Safety Related Comments to the NPRM

The agencies received safety related comments to the NPRM focused on the vehicle and operator safety benefits of central tire inflation systems, potential safety and traction impacts of low rolling resistance tires, and recommendations that NHTSA continue evaluations of potential safety impacts of fuel saving technologies.

AIR CTI, Inc., a supplier of central tire inflation systems, highlighted the safety benefits to both vehicle operation and the operators themselves through proper tire pressure management. More specifically, the proper tire inflation levels for the load being carried contributes to both proper handling for road conditions and reducing irregular road surface vibration from being transmission to vehicle component and, ultimately, the vehicle operator, where there may be potential health implications over prolonged exposure.

The agencies appreciate the additional points provided by AIR CTI in terms of not only the potential fuel efficiency benefits of central tire inflation systems but the potential equipment longevity benefits, vehicle dynamic impacts, and the potential to reduce driver fatigue and injury through proper tire inflation for the load being carried.

The American Trucking Associations (ATA) commented on the potential impact of Low Rolling Resistance Tires by indicating that, "The safety effects of LRRTs are not totally understood. While the ". . . agencies analysis indicate that this proposal should have no adverse impact on vehicle or engine safety," ATA remains leery of potential unintended consequences resulting from new generation tires that have yet to be developed. This especially holds true in terms of overall truck braking distances." The Owner-Operator Independent Drivers Association

(OOIDA) similarly commented on LRRTs and their ability to meet the tractions needs in mountainous regions.

The agencies continue to stand behind the low rolling resistance tire research conducted to date, which includes the study mentioned in the previous section, along with any research supporting the development, and maintenance, of FMVSS No. 121. The agencies agree, though, that continuing research will be important as new tire technologies enter the marketplace, and like the extensive rolling resistance testing conducting to support the Phase 1 regulation and, in part, this final rule, the agencies will continue to monitor developments in the tire supply marketplace through the EPA Smartway program and other, potential, research. NHTSA notes that FMVSS No. 121 will continue to play a role in ensuring the safety of both current and future tire technologies.

The ATA also expressed support for the NHTSA study mentioned in the previous section, *Review and Analysis of Potential Safety Impacts of and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles*. More specifically, ATA requested that DOT/NHTSA and the DOT Volpe Center continue "to assess and evaluate potential safety impacts that may be attributed to the use of fuel efficiency devices." The agencies appreciate ATA's support and acknowledge of this comprehensive, peer-reviewed assessment and we look forward to continuing this work to as the need arises.

(3) The Agencies' Assessment of Potential Safety Impacts

NHTSA and EPA considered the potential safety impact of technologies that improve MDHD vehicle fuel efficiency and GHG emissions as part of the assessment of regulatory alternatives and selection of the final regulatory approach. The safety assessment of the technologies in this final rule was informed by two NAS reports, an analysis of safety effects of HD pickups and vans using estimates from the DOT report on the effect of mass reduction and vehicle size on safety, and agency-sponsored safety testing and research. The agencies considered safety from the perspective of both direct effects and indirect effects.

In terms of direct effects on vehicle safety, research from NAS and Volpe, and direct testing of technologies like the ORNL tire work, indicate that there are no major safety hazards associated with the adoption of technologies that improve MDHD vehicle fuel efficiency

and GHG emissions or the increased use of alternative fuels and vehicle electrification. The findings suggest that the potential safety hazards identified during operation, maintenance, and crash scenarios can be prevented or mitigated by complying with safety regulations, voluntary standards, and industry best practices. Tire testing showed tire rolling resistance did not impact of Class 8 tractor-trailer stopping distance for the tires tested. For HD pickup and vans, mass reduction is anticipated to reduce the net incidence of highway fatalities, because of the beneficial effects of mass reduction in the majority of HD pickup and vans which weigh more than 4,594 lbs. Taken together, these studies suggest that the fuel efficiency improving technologies assessed in the studies can be implemented with no degradation in overall safety.

However, analysis anticipates that the indirect effect of these standards, by reducing the operating costs, will lead to increased travel by tractor-trailers and HD pickups and vans and, therefore, more crashes involving these vehicles.

X. Analysis of the Alternatives

As discussed in the NPRM and throughout this Preamble, in developing this program, the agencies considered a number of regulatory alternatives that could result in potentially fewer or greater GHG emission and fuel consumption reductions than the Phase 2 program we are adopting. This section summarizes the alternatives we considered and presents estimates of the CO₂ reductions and fuel savings associated with them. Although some of the alternatives considered for the FRM are identical to alternatives considered for the NPRM, the preferred alternative (*i.e.* the final rule) is actually more stringent than the preferred alternative that was proposed, and includes some elements of the NPRM's Alternative 4.

In developing alternatives, both agencies must consider a range of stringency. NHTSA must consider EISA's requirement for the MD/HD fuel efficiency program. In particular, 49 U.S.C. 32902(k)(2) and (3) contain the following three requirements specific to the MD/HD vehicle fuel efficiency improvement program: (1) The program must be "designed to achieve the maximum feasible improvement;" (2) the various required aspects of the program must be appropriate, cost-effective, and technologically feasible for MD/HD vehicles; and (3) the standards adopted under the program must provide not less than four model years of lead time and three model years of regulatory stability. In considering

these various requirements, NHTSA will also account for relevant environmental and safety considerations.

As explained in the Phase 1 rule, NHTSA has broad discretion in balancing the above factors in determining the improvement that the manufacturers can achieve. The fact that the factors may often be conflicting gives NHTSA significant discretion to decide what weight to give each of the competing policies and concerns and then determine how to balance them—as long as NHTSA's balancing does not undermine the fundamental purpose of the EISA: Energy conservation, and as long as that balancing reasonably accommodates “conflicting policies that were committed to the agency's care by the statute.”⁹³⁴

EPA also has significant discretion in considering a range of stringency. Section 202(a)(2) of the Clean Air Act requires only that the standards “take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” This language affords EPA considerable discretion in how to weight the critical statutory factors of emission reductions, cost, and lead time. See 76 FR 57129–57130.

The alternatives presented here follow the format of the alternatives addressed in the NPRM. Among the alternatives are a preferred alternative (in this action, the “final program”), more stringent alternatives, and less stringent alternatives (including “no action” alternatives). As discussed in this Preamble's Sections II (Engines), III (Tractors), IV (Trailers), V (Vocational Vehicles), and VI (Pickups and Vans), NHTSA and EPA determined Alternative 3 to be the preferred alternative, or the final program, for each vehicle category. This Section X describes all of the alternatives considered, and provides context for the relative stringency associated with the final program.

A. What are the alternatives that the agencies considered?

The five alternatives below represent a broad range of potential stringency levels, and thus a broad range of associated technologies, costs and benefits for a HD vehicle fuel efficiency and GHG emissions program. All of the alternatives were modeled using the same methodologies described in Chapter 5 of the RIA.

The alternatives considered for the final rule were conceptually similar to (and for some elements, identical to) the alternatives considered for the proposal. The alternatives in order of increasing fuel efficiency and GHG emissions reductions are as follows:

1. No action, baseline
2. Less stringent than the proposal
3. Preferred alternative
4. Proposed (not FRM) standards with less lead time
5. More stringent standards than the proposal with less lead time

Comments on the alternatives overlapped with comments on the overall stringency of the proposed Phase 2 program. These comments were mixed. Some operators and manufacturers supported the least stringent alternatives. Many other commenters, however, including most non-governmental organizations, supported more stringent standards with less lead time. They generally supported Alternative 4. Many technology and component suppliers supported more stringent standards but with the proposed lead time, and thus generally supported the Alternative 3 timeframe. Vehicle manufacturers strongly opposed the more stringent standards and reduced lead time of Alternative 4. To the extent any of these commenters provided technical information to support their comments on stringency and lead time, it is discussed in Sections II through VI.

Many of the comments supporting more stringent standards stated that they would be “cost-effective.” In general, however, we did not find costs or cost-effectiveness to be a significantly limiting factor in determining the stringency of the standards. Rather, we found that actual technological feasibility and lead time to be the more limiting factors. Manufacturers and suppliers have limited research and development capacities, and although they have some ability to expand, that ability is constrained by the lead time required. Lead time includes time not only to design and develop a technology, but to bring it to market in reliable form. During the prototype stage, all prototype components must be available and extensive engine and vehicle tests must be conducted. The production start-up phase would follow. After that, significant efforts must be made to advance the system from a prototype to a commercial product, which typically takes about five years for complex systems. During this approximate five-year period, multiple vehicles will go through weather condition tests, long lead-time parts and

tools will be identified, and market launch and initial results on operating stability will be completed. Production designs will be released, all product components should be made available, production parts on customer fleets and weather road testing will be verified before finally launching production, and distribution of parts to the vehicle service network for maintenance and repair will be readied. See Section I.C above; see also RIA Chapter 2.3.9. New technologies then are ordinarily phased into the commercial market, so that fleet operators are assured of technology reliability and utility before making extensive purchases. Commenters supporting the more stringent alternatives based on cost-effectiveness generally did not address these very real lead time constraints.

(1) Alternative 1: No Action (The Baseline for Phase 2)

OMB guidance regarding regulatory analysis indicates that proper evaluation of the benefits and costs of regulations and their alternatives requires agencies to identify a baseline:

“You need to measure the benefits and costs of a rule against a baseline. This baseline should be the best assessment of the way the world would look absent the proposed action. The choice of an appropriate baseline may require consideration of a wide range of potential factors, including:

- Evolution of the market
- changes in external factors affecting expected benefits and costs
- changes in regulations promulgated by the agency or other government entities
- degree of compliance by regulated entities with other regulations

It may be reasonable to forecast that the world absent the regulation will resemble the present. If this is the case, however, your baseline should reflect the future effect of current government programs and policies. For review of an existing regulation, a baseline assuming no change in the regulatory program generally provides an appropriate basis for evaluating regulatory alternatives. When more than one baseline is reasonable and the choice of baseline will significantly affect estimated benefits and costs, you should consider measuring benefits and costs against alternative baselines. In doing so you can analyze the effects on benefits and costs of making different assumptions about other agencies' regulations, or the degree of compliance with your own existing rules. In all cases, you must evaluate benefits and costs against the same baseline. You should also discuss

⁹³⁴ Cf. *Center for Biological Diversity v. National Highway Traffic Safety Admin.*, 538 F.3d 1172, 1194 (9th Cir. 2008). For further discussion see 76 FR 57198.

the reasonableness of the baselines used in the sensitivity analyses. For each baseline you use, you should identify the key uncertainties in your forecast.”⁹³⁵

A no-action alternative is also required as a baseline against which to measure environmental impacts of these standards and alternatives. NHTSA, as required by the National Environmental Policy Act, is documenting these estimated impacts in the EIS published with this final rule.⁹³⁶

The No Action Alternative for today's analysis, alternatively referred to as the “baseline” or “reference case,” assumes that the agencies would not issue new rules regarding MD/HD fuel efficiency and GHG emissions. That is, this alternative assumes that the Phase 1 MD/HD fuel efficiency and GHG emissions program's model year 2018 standards would be extended indefinitely and without change.

The agencies recognize that there are a number of factors that create uncertainty in projecting a baseline against which to compare the future effects of the alternatives. The composition of the future fleet—such as the relative position of individual manufacturers and the mix of products they each offer—cannot be predicted with certainty at this time. As reflected, in part, by the market forecast underlying the agencies' analysis, we anticipate that the baseline market for medium- and heavy-duty vehicles will continue to evolve within a competitive market that responds to a range of factors. Additionally, the heavy-duty vehicle market is diverse, as is the range of vehicle purchasers.

Heavy-duty vehicle manufacturers have reported that their customers' purchasing decisions are influenced by their customers' own determinations of minimum total cost of ownership, which can be unique to a particular

customer's circumstances. For example, some customers (e.g., less-than-truckload or package delivery operators) operate their vehicles within a limited geographic region and typically own their own vehicle maintenance and repair centers within that region. These operators tend to own their vehicles for long time periods, and sometimes for the entire service life of the vehicle. Their total cost of ownership is influenced by their ability to better control their own maintenance costs, and thus they can afford to consider fuel efficiency technologies that have longer payback periods, outside of the vehicle manufacturer's warranty period. Other customers (e.g. truckload or long-haul operators) tend to operate cross-country, and thus must depend upon truck dealer service centers for repair and maintenance. Some of these customers tend to own their vehicles for about four to seven years, so that they typically do not have to pay for repair and maintenance costs outside of either the manufacturer's warranty period or some other extended warranty period. Many of these customers tend to require seeing evidence of fuel efficiency technology payback periods on the order of 18 to 24 months before seriously *considering* evaluating a new technology for potential adoption within their fleet.⁹³⁷ Purchasing decisions, however, are not based exclusively on payback period, but also include the considerations discussed in this section. For the baseline analysis, the agencies use payback period as a proxy for all of these considerations, and therefore the payback period used for the baseline analysis may be shorter than the payback periods industry typically identifies as thresholds for the further consideration of a technology. Some owners accrue relatively few vehicle miles traveled per year, such that they may be less likely to adopt new fuel efficiency technologies, while other owners who use their vehicle(s) with greater intensity may be even more willing to pay for fuel efficiency improvements. Regardless of the type of customer, their determination of minimum total cost of ownership involves the customer balancing their own unique circumstances with a heavy-duty vehicle's initial purchase price, availability of credit and lease options, expectations of vehicle reliability, resale value and fuel efficiency technology payback periods. The degree of the incentive to adopt additional fuel efficiency technologies also depends on customer expectations

of future fuel prices, which directly impacts customer expectations of the payback period.

Another factor the agencies considered is that other federal and state-level policies and programs are specifically aimed at stimulating fuel efficiency technology development and deployment. Particularly relevant to this sector are DOE's 21st Century Truck Partnership, EPA's voluntary SmartWay Transport program, and California's AB32 fleet requirements.^{938 939 940} The future availability of more cost-effective technologies to reduce fuel consumption could provide manufacturers an incentive to produce more fuel-efficient medium- and heavy-duty vehicles, which in turn could provide customers an incentive to purchase these vehicles. The availability of more cost-effective technologies to reduce fuel consumption could also lead to a substitution of less cost-effective technologies, where overall fuel efficiency could remain fairly flat if buyers are less interested in fuel consumption improvements than in reduced vehicle purchase prices and/or improved vehicle performance and/or utility.

We have also applied the EIA's AEO estimates of future fuel prices; however, heavy-duty vehicle customers could have different expectations about future fuel prices, and could therefore be more or less inclined to apply new technology to reduce fuel consumption than might be expected based on EIA's forecast. We expect that vehicle customers will be uncertain about future fuel prices, and that this uncertainty will be reflected in the degree of enthusiasm to apply new technology to reduce fuel consumption.

Considering all of these factors, the agencies have approached the definition of the No Action Alternative separately for each vehicle and engine category covered by today's rules. Except as noted below, these baselines are largely the same as the proposed Alternatives 1a and 1b, which reflected different assumptions about the extent to which the market would pay for additional fuel-saving technology without new Phase 2 standards. The agencies received limited comments on these reference cases. Some commenters expressed support for the 1a baseline in the context of the need for the regulations, arguing that little improvement would occur without the regulations. Others supported the 1a

⁹³⁵ OMB Circular A-4, September 17, 2003. Available at http://www.whitehouse.gov/omb/circulars_a004_a-4.

⁹³⁶ NEPA requires agencies to consider a “no action” alternative in their NEPA analyses and to compare the effects of not taking action with the effects of the reasonable action alternatives to demonstrate the different environmental effects of the action alternatives. See 40 CFR 1502.2(e), and 1502.14(d). CEQ has explained that “[T]he regulations require the analysis of the no action alternative even if the agency is under a court order or legislative command to act. This analysis provides a benchmark, enabling decision makers to compare the magnitude of environmental effects of the action alternatives. [See 40 CFR 1502.14(c).]” * * * Inclusion of such an analysis in the EIS is necessary to inform Congress, the public, and the President as intended by NEPA. [See 40 CFR 1500.1(a).]” Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, 46 FR 18026 (1981) (emphasis added).

⁹⁴⁰ State of California Global Warming Solutions Act of 2006 (Assembly Bill 32, or AB32).

baseline because they believe it more fully captures the costs. Some commenters thought it reasonable that the agencies consider both baselines, given the uncertainty in this area. No commenters opposed the consideration of both baselines. The agencies thus continued to analyze two different baselines for the final rules as we recognize that there are a number of factors that create uncertainty in projecting a baseline against which to compare the future effects of this action and the remaining alternatives. As was shown in the previous sections, the standards are supported by the analysis using either baseline.

For trailers, the agencies considered two No Action alternatives to cover a nominal range of uncertainty. The trailer category is unique in the context of this rulemaking because it is the only heavy-duty category not regulated under Phase 1. The agencies project that in 2018, about half of new 53' dry van and reefer trailers will have technologies qualifying for the SmartWay label for aerodynamic improvements and about 90 percent would have the lower rolling resistance tires. About half also have automatic tire inflation systems to maintain optimal tire pressure. For Alternative 1a as presented in this action (referred to as the "flat" baseline), this technology adoption remains constant after 2018. In the second case, Alternative 1b, the agencies projected that the combination of EPA's voluntary SmartWay program, DOE's 21st Century Truck Partnership, California's AB32 trailer requirements for fleets, and the potential for significantly reduced operating costs should result in continuing improvement to new trailers. The agencies projected that the fraction of the in-use fleet qualifying for SmartWay will continue to increase beyond 2027 as older trailers are replaced by newer trailers. We projected that these improvements will continue until 2040 when 75 percent of new trailers will be assumed to include skirts.

For vocational vehicles, the agencies considered one No Action alternative. For the vocational vehicle category the agencies recognized that these vehicles tend to operate over fewer vehicle miles travelled per year. Therefore, the projected payback periods for fuel efficiency technologies available for vocational vehicles are generally longer than the payback periods the agencies consider likely to lead to their adoption based solely on market forces. This is especially true for vehicles used in applications in which the vehicle operation is secondary to the primary business of the company using the

vehicle. For example, since the fuel consumption of vehicles used by utility companies to repair power lines would generally be a smaller cost relative to the other costs of repairing lines, fuel saving technologies would generally not be as strongly demanded for such vehicles. Thus, the agencies project that fuel-saving technologies will either not be applied or will only be applied as a substitute for more expensive fuel efficiency technologies, except as necessitated by the Phase 1 fuel consumption and GHG standards.

For tractors, the agencies considered two No Action alternatives to cover a nominal range of uncertainty. For Alternative 1a the agencies project that fuel-saving technologies will either not be applied or will only be applied as a substitute for more expensive fuel efficiency technologies to tractors (thereby enabling manufacturers to offer tractors that are less expensive to purchase), except as necessitated by the Phase 1 fuel consumption and GHG standards. In Alternative 1b the agencies estimated that some available technologies will save enough fuel to pay back fairly quickly—within the first six months of ownership. The agencies considered a range of information to formulate these two baselines for tractors.

Both public⁹⁴¹ and confidential historical information shows that tractor trailer fuel efficiency improved steadily through improvements in engine efficiency and vehicle aerodynamics over the past 40 years, except for engine efficiency which decreased or was flat between 2000 and approximately 2007 as a consequence of incorporating technologies to meet engine emission regulations. Today vehicle manufacturers, the Federal Government, academia and others continue to invest in research to develop fuel efficiency improving technologies for the future.

In public meetings and in meetings with the agencies, the trucking industry stated that fuel cost for tractors is the number one or number two expense for many operators, and therefore is a very important factor for their business. However, the pre-Phase 1 market suggests that tractor manufacturers and operators could be slow to adopt some

new technologies, even where the agencies have estimated that the technology would have paid for itself within a few months of operation. This phenomenon, which is discussed in Section IX.A, is often called the energy paradox. Consistent with the discussion above of reasons for needed lead time, tractor operators have told the agencies they generally require technologies to be demonstrated in their fleet before widespread adoption so they can assess the actual fuel savings for their fleet and any increase in cost associated with effects on vehicle operation, maintenance, reliability, mechanic training, maintenance and repair equipment, stocking unique parts and driver acceptance, as well as effects on vehicle resale value. Tractor operators often state that they would *consider* conducting an assessment of technologies when provided with data that show the technologies may payback costs through fuel savings within 18 to 24 months, based on their assumptions about future fuel costs. In other words they would treat this as a necessary condition, but generally would not consider it to be sufficient. In these cases, an operator may first conduct a detailed paper study of anticipated costs and benefits. If that study shows likely payback in 18 to 24 months for their business, the fleet may acquire one or several tractors with the technology to directly measure fuel savings, costs and driver acceptance for their fleet. Small fleets may not have resources to conduct assessments to this degree and may rely on information from larger fleets or observations of widespread acceptance of the technology within the industry before adopting a technology. This uncertainty over the actual fuel savings and costs and the lengthy process to assess technologies significantly slows the pace at which fuel efficiency technologies are adopted.

The agencies believe that using the two baselines addresses the uncertainties we have identified for tractors. The six-month payback period of Alternative 1b reflects the agencies' consideration of factors, discussed above, that could limit—yet not eliminate—manufacturers' tendencies to voluntarily improve fuel consumption. In contrast, Alternative 1a reflects a baseline for vehicles other than trailers wherein manufacturers either do not apply fuel efficiency technologies or only apply them as a substitute for more expensive fuel efficiency technologies, except as necessitated by the Phase 1 fuel consumption and GHG standards.

For HD pickups and vans, the agencies considered two No Action alternatives to cover a nominal range of

⁹⁴¹ Committee to Assess Fuel Economy Technologies for Medium- and Heavy-Duty Vehicles; National Research Council; Transportation Research Board (2010). "Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles," (hereafter, "NAS 2010"). Washington, DC: The National Academies Press. Available electronically from the National Academies Press Web site at http://www.nap.edu/catalog.php?record_id=12845 (last accessed September 10, 2010).

uncertainty. In Alternative 1b the agencies considered additional technology application, which involved the explicit estimation of the potential to add specific fuel-saving technologies to each specific vehicle model included in the agencies' HD pickup and van fleet analysis, as discussed in Section VI. Estimated technology application and corresponding impacts depend on the modeled inputs. Also, under this approach a manufacturer that has improved fuel consumption and GHG emissions enough to achieve compliance with the standards is assumed to apply further improvements, provided those improvements reduce fuel outlays by enough (within a specified amount of time, the payback period) to offset the additional costs to purchase the new vehicle. These calculations explicitly account for and respond to fuel prices, vehicle survival and mileage accumulation, and the cost and efficacy of available fuel-saving technologies. Therefore, all else being equal, more technology is applied when fuel prices are higher and/or technology is more cost-effective. However, considering factors discussed above that could limit manufacturers' tendency to voluntarily improve HD pickup and van fuel consumption, Alternative 1b applies a 6-month payback period. In contrast, for Alternative 1a, the agencies project that fuel-saving technologies will either not be applied or only be applied as a substitute for more expensive fuel efficiency technologies, except as necessitated by the Phase 1 fuel consumption and GHG standards. The Method A sensitivity analysis presented in Section VI of the NPRM also examined other payback periods. In terms of impacts under reference case fuel prices, the payback period input plays a more significant role under the No-Action Alternatives (defined by a continuation of model year 2018 standards) than under the more stringent regulatory alternatives for HD pickups and vans described next.

(2) Alternative 2: Less Stringent Than the Preferred Alternative

For vocational vehicles and combination tractor-trailers, Alternative 2 represents a stringency level which is approximately half as stringent overall as the final standards. The agencies developed Alternative 2 to consider a continuation of the Phase 1 approach of applying off-the-shelf technologies rather than requiring the development of new technologies or fundamental improvements to existing technologies. For tractors and vocational vehicles, this also involved less integrated optimization of the vehicles and

engines. Put another way, Alternative 2 is not technology-forcing.⁹⁴² See, e.g., *Sierra Club v. EPA*, 325 F. 3d 374, 378 (D.C. Cir. 2003) (under a technology-forcing provision, EPA "must consider future advances in pollution control capability"); see also similar discussion in *Husqvarna AB v. EPA*, 254 F. 3d 195, 201 (D.C. Cir. 2001).

The agencies' decisions regarding which technologies could be applied to comply with Alternative 2 considered not only the use of off-the shelf technologies, but also considered other factors, such as how broadly certain technologies fit in-use applications and regulatory structure. The resulting Alternative 2 could be met with fewer technologies and lower penetration rates than those the agencies project will be used to meet the final Phase 2 standards. Alternative 2 is estimated to be achievable without the application of some technologies, at any level. These and other differences are described below by category. Overall, Alternative 2 for the final rules is conceptually similar to Alternative 2 in the NPRM. However, some changes have been made to reflect new information provided in public comments.

The agencies project that Alternative 2 combination tractor standards could be met by applying lower adoption rates of the projected technologies for Alternative 3. This includes a projection of slightly lower per-technology effectiveness for Alternative 2 versus 3. Alternative 2 also assumes that there would be little optimization of combination tractor powertrains.

The Alternative 2 for vocational vehicles assessed for these final rules does differ somewhat from the proposal because it reflects new duty cycles that weight idle emissions more heavily. The agencies project that the Alternative 2 vocational vehicle standard could be met without any use of strong hybrids or any other type of transmission technology. Rather, it could be met with off-the-shelf idle reduction technologies, low rolling resistance tires, and axle efficiency improvements.

The Alternative 2 trailer standards would apply to only 53-foot dry and refrigerated box trailers and could be met through the use of less effective aerodynamic technologies and higher rolling resistance tires versus what the

agencies projected could be used to meet Alternative 3 (*i.e.*, the final standards).

As discussed above in Section VI, the HD pickup truck and van alternatives are characterized by an annual required percentage change (decrease) in the functions defining attribute-based targets for per-mile fuel consumption and GHG emissions. Under the standards in each alternative, a manufacturer's fleet would, setting aside any changes in production mix, be required to achieve average fuel consumption/GHG levels that increase in stringency every year relative to the standard defined for MY 2018 (and held constant through 2020) that establishes fuel consumption/GHG targets for individual vehicles. A manufacturer's specific fuel consumption/GHG requirement is the sales-weighted average of the targets defined by the work-factor curve in each year. Therefore, although the alternatives involve steady increases in the functions defining the targets, stringency increases faced by any individual manufacturer may not be steady if changes in the manufacturer's product mix cause fluctuations in the average fuel consumption and GHG levels required of the manufacturer. See Section VI for additional discussion of this topic. Alternative 2 represents a 2.0 percent annual improvement through 2025 in fuel consumption/GHG emissions relative to the work-factor curve in 2020. This would be 0.5 percent less stringent per year compared to the standards of Alternative 3.

For HD pickups and vans in the Method A analysis, NHTSA projects that most manufacturers could comply with the standards defining Alternative 2 by applying technologies similar to those that could be applied in order to comply with the Alternative 3 standards, but at lower application rates. In EPA's Method B analysis, the biggest technology difference EPA projects between Alternative 2 and the Alternative 3 final standards is that most manufacturers could meet the Alternative 2 standards without any use of stop-start or other mild or strong hybrid technologies.

The agencies are not adopting standards reflecting Alternative 2 for reasons of both policy and law. Technically feasible alternate standards are available that provide for greater emission reductions and reduced fuel consumption than provided under Alternative 2. These more stringent standards, which are being adopted, are feasible at reasonable cost, considering both per-vehicle and per-engine cost, cost-effectiveness, direct benefits to

⁹⁴² As noted in Section I.C, in this context, the term "technology-forcing" has a specific legal meaning and is used to distinguish standards that will effectively require manufacturers to develop new technologies (or to significantly improve technologies) from standards that can be met using off-the-shelf technology alone. Technology-forcing standards do not require manufacturers to use any specific technologies.

consumers in the form of fuel savings, and lead time. Consequently, the agencies do not believe that the modest improvements in Alternative 2 would be appropriate or otherwise reasonable under section 202(a)(1) and (2) of the Clean Air Act, or represent the “maximum feasible improvement” within the meaning of 49 U.S.C. 32902(k)(2).

(3) Alternative 3: Preferred Alternative and Final Standards

The agencies are adopting Alternative 3 for HD engines, HD pickup trucks and vans, Class 2b through Class 8 vocational vehicles, Class 7 and 8 combination tractors, and trailers. Details regarding modeling of this final program are included in Chapter 5 of the RIA. Note that Alternative 3 for the final rules differs from the Alternative 3 in the NPRM. The differences are largely in response to significant comments on the proposed rule. Although some aspects of the final Alternative 3 are more aggressive than proposed (including adopting some aspects of the proposed Alternative 4), others are less aggressive. As a result of these changes, the preferred alternative in this final rule is projected to achieve more GHG emission reductions and more reductions of fuel consumption than the proposed alternative 4. See Section X.B below and RIA Chapter 5.

Unlike the Phase 1 standards where the agencies projected that manufacturers could meet the Phase 1 standards with off-the-shelf technologies only, the agencies project that meeting the Alternative 3 standards will require a combination of off-the-shelf technologies applied at higher market penetration rates and new technologies that are still in various stages of development and not yet in production. Although this alternative is technology-forcing, it must be kept in mind that the standards themselves are performance-based and thus do not mandate that any particular technology be used to meet the standards.⁹⁴³ The agencies recognize that there is some uncertainty in projecting costs and effectiveness for those technologies not yet available in the market, but we do not believe, as discussed comprehensively in Sections II, III, IV, V, and VI, that such uncertainty is sufficient to render Alternative 3 beyond the reasonable or maximum feasible level of stringency for each of the engine and vehicle categories covered by this program. Moreover, we have explained what steps will be

needed to bring these technologies to the commercial market, and the lead time needed to do so. Given that nearly all of the final standards are performance-based rather than mandates of specific technologies, and given that the lead time for the most stringent standards in Alternative 3 is approximately 10 years, the agencies believe that the performance that is required by these stringency levels of Alternative 3 allows each manufacturer to choose to develop technology and apply it to their vehicles (and engines, where applicable) in a way that balances their unique business constraints and reflects their specific market position and customers’ needs.⁹⁴⁴

We have described in detail above, and also in Chapter 2 of the RIA, the precise bases for each of these standards (that is, for each segment covered under the program). Sections II through VI of this Preamble provide comprehensive explanations of the agencies’ assessment of the extent to which such standards could be met through the accelerated application of technologies and our reasons for concluding that the identified technologies for each of the vehicle and engine standards that constitute the updated Alternative 3 represent the maximum feasible (within the meaning of 49 U.S.C. 32902 (k)) and reasonable (for purposes of CAA section 202(a)(1) and (2)) based on all of the information available to the agencies at the time of this rulemaking. In particular, the agencies determined that many engine improvements could be achieved sooner than we projected in our NPRM analysis, some even sooner than projected as part of the Alternative 4 analysis.

(4) Alternative 4: More Accelerated Than the Preferred Alternative in the NPRM

As indicated by its description in the title above, Alternative 4 represents standards that are effective on a more accelerated timeline in comparison to the timeline of in the proposed Alternative 3 standards. This alternative is unchanged from Alternative 4 in the proposal. The agencies believe that reanalyzing the same Alternative 4 provides a useful context for commenters who supported the proposed Alternative 4.

In the NPRM, Alternatives 3 and 4 were both designed to achieve similar fuel efficiency and GHG emission levels in the long term but with Alternative 4

being accelerated in its implementation timeline. Specifically, Alternative 4 reflects the same or similar standard stringency levels as the proposed Alternative 3, but 3 years sooner (2 years for heavy-duty pickups and vans), so that the final phase of the standards would occur in MY 2024, or (for heavy duty pickups and vans) 2025.

The agencies projected in the NPRM that meeting Alternative 4 combination tractor standards would require applying initially higher adoption rates of the projected technologies for Alternative 3. This included a projection of slightly higher per-technology effectiveness for Alternative 4 versus 3. Alternative 4 also assumes that there would be more optimization of combination tractor powertrains and earlier market penetration of engine waste heat recovery systems.

The agencies also projected that meeting the Alternative 4 vocational vehicle standard would require earlier adoption rates of the same technology packages projected for Alternative 3.

Meeting the Alternative 4 trailer standards would require earlier implementation of more effective aerodynamic technologies, including the use of aerodynamic skirts and boat tails. This would be in addition to implementing lower rolling resistance tires for nearly all trailers.

HD pickup truck and van standards defining Alternative 4 represent a 3.5 percent annual improvement in fuel consumption and GHG emissions through 2025 relative to the work-factor curves in 2020. This would require earlier adoption of all the Alternative 3 technologies.

As discussed above and in the feasibility discussions in Sections II–VI, we are adopting those elements of the proposed Alternative 4 where we have determined them to be feasible in the lead time provided. However, the agencies have determined that it is unlikely that all elements of Alternative 4 could be achieved by 2024. In fact, the agencies can only project that the engine improvements and some tire improvements will be achievable on the Alternative 4 timeline. Thus, we do not believe these alternative standards to be feasible overall, and we are consequently unable to accurately estimate costs for them. The agencies received many comments supporting the Alternative 4 standards where the commenter noted they supported them because they would be “cost-effective” based on the proposed analysis of costs. However, we do not consider this conclusion to be accurate. We do not believe the proposed analysis fully represents the costs for this alternative

⁹⁴³ The one exception being design standards for certain non-aero trailers.

⁹⁴⁴ Those few standards that are design-based rather than performance based reflect comments indicating that performance-based flexibility would not be necessary or helpful for certain markets.

because it included little additional costs related to pulling ahead the development of so many additional technologies. It also does not reflect any costs associated with a decrease in the in-use reliability and durability during the initial years of implementation. It does not reflect costs of design and deployment outside of normal design cycles, an example being the necessity of developing new engine platforms if WHR were to be applied at higher penetration rates by MY 2024. See RIA Chapter 2.7.5. As we have already noted, we did not find costs or cost-effectiveness to be a significantly limiting factor in determining the stringency of the standards. Rather, we found that actual technological feasibility and lead time to be the more limiting factors. In this respect, we found Alternative 4 to provide insufficient lead time for any of the standards—engine, pickups and vans, vocational vehicles, tractors, and trailers.

(5) Alternative 5: Even More Stringent Standards With Less Lead-Time

Alternative 5 represents even more stringent standards compared to Alternatives 3 and 4, as well as the same implementation timeline as Alternative 4. As discussed in the NPRM, and as repeated above and in the feasibility discussions in Sections II–VI, we are not adopting Alternative 5 because we cannot project that manufacturers can develop and introduce in sufficient quantities the technologies that could be used to meet Alternative 5 standards. No commenters provided any new information to refute this finding. We believe that for some or all of the categories, the Alternative 5 standards are simply technically infeasible within the lead time allowed. We have not fully

estimated costs for this alternative for tractors and vocational vehicles because we believe that there would be such substantial additional costs related to pulling ahead the development of so many additional technologies that we cannot accurately predict these costs. (Indeed, how can cost estimates for an alternative which essentially cannot be done at all be realistic?) We also believe this alternative, if it could somehow be effectuated, would result in a decrease in the in-use reliability and durability of new heavy-duty vehicles and that we do not have the ability to accurately quantify the costs that would be associated with such problems. Instead, we merely note that costs would be significantly greater than the estimated costs for Alternative 3, assuming (against our view) that such standards would be feasible at all.

B. How do these alternatives compare in overall fuel consumption and GHG emissions reductions?

The following tables compare the overall fuel consumption and GHG emissions reductions of each of the regulatory alternatives the agencies considered.

Note that for tractors, trailers, pickups and vans the agencies compared overall fuel consumption and GHG emissions reductions relative to two different baselines, described above in the section on the No Action alternative. Therefore, for tractors, trailers, pickups and vans two results are listed; one relative to each baseline, namely Alternative 1a and Alternative 1b.

Also note that the agencies analyzed pickup and van overall fuel consumption and emissions reductions and benefits and costs using the NHTSA's CAFE model (Method A). In addition, the agencies used EPA's

MOVES model to estimate pickup and van fuel consumption and emissions and a cost methodology that applied vehicle costs in different model years (Method B). In both cases, the agencies used a version of the CAFE model to estimate average per vehicle cost, and this analysis extended through model year 2030.⁹⁴⁵ The agencies concluded that in these instances the choice of baseline and the choice of modeling approach (Method A versus Method B) did not impact the agencies' decision to finalize Alternative 3.

The agencies are finalizing a more stringent program than proposed, so that the preferred alternative for the FRM (Alternative 3) achieves greater reductions and net benefits than the proposed program would have. Moreover, because the agencies analyzed the same Alternative 4 for the FRM as for the NPRM, the FRM preferred alternative also achieves greater reductions than Alternative 4 would have.

The regulatory impact analysis (RIA) accompanying today's notice presents more detailed results of the agencies' analysis.

(1) Impacts Using Analysis Method A

Table X–1 through Table X–4 summarize the key NHTSA estimates of the costs and benefit of the program using Method A. The first two tables show the costs and benefits using a 3 percent discount rate under both the flat and dynamic baselines. The third and fourth tables show the costs and benefits using a 7 percent discount rate for both baselines. Under all possible combinations of discount rate and baseline the net benefits from highest to lowest are as follows: Alternative 5; Alternative 3; Alternative 4; Alternative 2.

TABLE X–1—MY 2018–2029 LIFETIME SUMMARY OF PROGRAM BENEFITS AND COSTS, DISCOUNTED AT 3% (RELATIVE TO BASELINE 1a), METHOD A^a

Vehicle segment	Alt 2	Alt 3	Alt 4	Alt 5
Discounted pre-tax fuel savings (\$billion)				
HD pickups and Vans	12.1	18.7	20.3	22.3
Vocational Vehicles	13.5	25.5	23.6	34.6
Tractors/Trailers	50.2	118.8	115.7	169.1
Total	75.7	163.0	159.6	225.9
Discounted Total technology costs (\$billion)

XI. Natural Gas Vehicles and Engines

NGV America estimates that approximately 65,200 natural gas trucks were operating in the U.S. in 2014. This represents 0.3 percent of the heavy-duty vehicle fleet in the U.S. based on EPA’s estimated 17.5 million heavy-duty trucks operating in the U.S.^{946 947} While medium and heavy-duty natural gas vehicles continue to be produced and sold, the collapse of crude oil prices starting in 2014 has reduced the economic incentive to expand the use of natural gas fueled trucks. Although these natural gas versions are similar in many ways to their petroleum counterparts, there are significant differences. There are also both similarities and differences in the production and distribution of natural gas relative to gasoline and diesel fuel.

This combined rulemaking by EPA and NHTSA is designed to regulate two separate characteristics of heavy-duty vehicles: Emissions of GHGs and fuel consumption (especially petroleum fuels). The use of natural gas as a heavy-duty fuel can impact both of these. In the case of diesel or gasoline powered vehicles, there is a close relationship between GHG emissions and petroleum consumption. The situation is different

for non-petroleum fuels like natural gas. Natural gas also has a lower carbon content than petroleum fuels. Thus, a natural gas vehicle that could achieve the same fuel efficiency as a diesel-powered vehicle would emit about 20 percent less CO₂ when operating on natural gas and consume no petroleum. A natural gas vehicle with the same fuel efficiency as a gasoline vehicle would emit about 30 percent less CO₂.⁹⁴⁸ However, current natural gas engines are 5 to 15 percent less energy efficient than diesel engines. This means that, although natural gas engines are typically less fuel efficient, they can have lower CO₂ emissions and consume much less petroleum. In Phase 1, the agencies balanced these factors by applying the gasoline and diesel CO₂ standards to natural gas engines based on the engine type of the natural gas engine. Fuel consumption for these vehicles is then calculated according to their tailpipe CO₂ emissions. In essence, this applies a one-to-one relationship between fuel efficiency and tailpipe CO₂ emissions for all vehicles, including natural gas vehicles. The agencies determined that this approach would likely create a small balanced incentive for natural gas use. See 76 FR 57123; see

also 77 FR 51705 (August 24, 2012) and 77 FR 51500 (August 27, 2012) (EPA and NHTSA, respectively, further elaborating on basis for having Phase 1 apply at the tailpipe only, including for alternative fueled vehicles); see also *Delta Construction Co. v. EPA*, 783 F. 3d 1291 (D.C. Cir. 2015) (dismissing challenge to Phase 1 GHG standards as being arbitrary for applying only on a tailpipe basis).

For Phase 2, the agencies have reevaluated the potential use of natural gas in the heavy-duty sector and the impacts of such use. As discussed below, based on our review of the literature and external projections we believe that the use of natural gas is unlikely to become a major fuel source for medium and heavy-duty vehicles during the Phase 2 time frame. Thus, since we project natural gas vehicles to have little impact on both overall GHG emissions and fuel consumption during the Phase 2 time frame, the agencies see no need to make fundamental changes to the Phase 1 approach for natural gas engines and vehicles.

As part of this rulemaking, the agencies developed a lifecycle analysis of natural gas used by the heavy-duty truck sector, which is presented in Section XI.B. We also present the results of analyses projecting the future use of natural gas by heavy-duty trucks, identify a number of potential emission control technologies, and discuss the

⁹⁴⁶ Yborra, Stephen; NGV Market Briefing to EPA and NHTSA, August 12, 2014.

⁹⁴⁷ MOVES2014; <http://www3.epa.gov/otaq/models/moves/index.htm>.

⁹⁴⁸ Methane emissions above the heavy-duty 0.1 g/bhp-hr methane tailpipe standard must be accounted for and offsets the lower CO₂ tailpipe emissions.

approaches that could help to reduce the methane emissions from natural gas trucks in the future. A more detailed discussion of these analyses and issues can be found in RIA Chapter 13.

A. Natural Gas Engine and Vehicle Technology

Both gasoline and diesel vehicles can be designed or modified to use natural gas. Several engine parameters and characteristics come into play in comparing engines powered by natural gas with engines powered by conventional fuels.

Gasoline-fueled engines are typically spark-ignition engines that rely on stoichiometric combustion, which means that essentially all the oxygen from the engine's intake air is consumed in the combustion process. Converting a gasoline-fueled engine to run on natural gas involves changing the hardware used to store and deliver fuel to the engine, but the combustion strategy remains largely unchanged. The engine must be recalibrated for the different fuel properties, but combustion typically remains stoichiometric. In addition, the catalysts may require significant changes to enable the heavy-duty engine to comply with the emission standards.

Diesel-fueled engines are compression-ignition engines that rely on lean-burn combustion, which means that the engine takes in a substantial quantity of excess air (oxygen) that is not consumed in the combustion process. Engines usually have turbochargers to compress the intake air, which allows for greater power output and thermodynamic efficiency. Converting a diesel-fueled engine to run on natural gas may involve a minimal set of changes to engine calibrations to maintain lean-burn operation and the overall operating characteristics of a compression-ignition engine, although there are substantial changes to the fuel storage and delivery systems. Compressed ignition natural gas engines either require the use of a pilot injection of a small amount of diesel fuel to initiate the combustion event when the natural gas is directly injected, or more commonly, a mixture (never more than 50 percent natural gas) of natural gas and diesel fuel is combusted for fumigated natural gas engines. It is also possible to convert a diesel-fueled engine to run on natural gas by adding a spark plug. The option of changing the calibration strategy to rely on stoichiometric combustion would allow for simpler engine design and operation, but it would come at a cost of higher fuel consumption and CO₂ emissions.

Engines running on natural gas are capable of meeting the same criteria and GHG emission standards that apply for gasoline and diesel engines, although complying with the methane tailpipe emission standard has posed a challenge for engine manufacturers up to this point. In the case of reducing PM and CO₂ emissions, there is an inherent advantage for natural gas. In contrast, engines must be properly calibrated and maintained to avoid high emission rates for NO_x, HC, and CO.

On-vehicle fuel storage for natural gas is also an important design parameter. The most common method today is compressed natural gas (CNG), which involves storing the fuel as a gas at very high pressure (up to ~3600 psi) to increase the density of the fuel, although the fuel remains less dense than diesel fuel. Compared to diesel fuel, CNG increases vehicle weight (because of heavier high pressure fuel tanks) and generally reduces the range relative to gasoline or diesel vehicles. Nevertheless, CNG technology is readily available and does not involve big changes for operators. The alternative is to extensively cool the fuel so that it can be stored as liquefied natural gas (LNG) at a lower pressure, which involves more extensive hardware changes for managing the fuel as a cryogenic liquid. LNG fuel storage also involves a substantial weight increase, but LNG has a higher density than CNG so LNG vehicles can store much more fuel than CNG vehicles in the same volume. LNG technology is available for a limited number of truck models, mostly for line-haul service where range is a paramount consideration. The cryogenic fuel requires substantial changes in hardware and procedures for refueling stations and operators. An additional difference from CNG is that because LNG must be kept cool to prevent evaporation, significant losses will occur if a vehicle is not used frequently enough. For example, an LNG vehicle left parked over a period of multiple days will eventually vent the fuel to prevent tank failure, as the system takes on heat from the surrounding environment and the pressure increases.

B. GHG Lifecycle Analysis for Natural Gas Vehicles

This section is organized into three sections. The first section summarizes the upstream emissions associated with natural production and distribution. The second section summarizes the downstream emissions associated with the actual use of the fuel. The last section summarizes the results of the lifecycle emissions analysis and provides a comparison between natural

gas lifecycle and diesel fuel lifecycle emissions. Only the overall results of the lifecycle emissions analysis between natural gas and diesel fuel are presented here, with more detail provided in Chapter 13 of the RIA.

(1) Upstream Emissions

Upstream methane emissions (occurring in natural gas production, processing, transmission, storage and distribution) have been estimated and summarized in the annual EPA report Inventory of U.S. Greenhouse Gas Emissions and Sinks (GHG Inventory) for the United Nations Framework Convention on Climate Change (UNFCCC). As a basis for estimating the lifecycle impact of natural gas use by heavy-duty trucks, we used the year 2014 methane emission estimates in the most recent GHG Inventory, published in 2016. Substantial amounts of new information on methane emissions from oil and gas systems have become available recently from a number of channels, including EPA's GHG Reporting program, industry organizations, and various research studies. EPA reviewed this information and revised its estimates of methane emissions from natural gas and petroleum facilities for the 2016 GHG Inventory. Comparing the most recent GHG Inventory estimate for 2013 to the previous GHG Inventory for 2013, methane emissions are about one third higher for the aggregated natural gas system than the previous estimate. The GHG Inventory also includes the quantity of carbon dioxide which is coproduced with methane throughout the natural gas system and emitted to the atmosphere through venting, flaring, and as fugitive emissions. Since the GHG Inventory only represents U.S.-based methane and carbon dioxide emissions, it does not estimate the GHG emissions caused by the production of natural gas in Canada which is imported to the U.S. The imported Canadian natural gas comprises about 10 percent of U.S. natural gas consumption. To estimate the GHG emissions from this Canadian natural gas, we assume that it has the same GHG emissions profile as U.S.-produced natural gas.

The GHG Inventory is updated annually to account for new emission sources (e.g., new natural gas wells), updated data, emission factors and/or methodologies, and to account for changes in emissions due to policy changes, regulatory changes and changes in industry practices. The GHG Inventory reflects emission reductions due to existing state regulations, National Emission Standards for Hazardous Air Pollutants (NESHAP)

promulgated by EPA in 1999,⁹⁴⁹ the New Source Performance Standards (NSPS) promulgated by EPA in 2012,⁹⁵⁰ and Natural Gas Star (a flexible, voluntary partnership that encourages oil and natural gas companies to adopt proven, cost-effective technologies and practices that improve operational efficiency and reduce methane emissions).⁹⁵¹

Emission estimates in the GHG Inventory are generally bottom-up estimates which are per-unit (compressor, pneumatic valve, etc.) emission estimates based on measured or calculated emission rates from such emission sources.

In addition to the national-level data available through the GHG Inventory, facility-level petroleum and natural gas systems data are also available through EPA's Greenhouse Gas Reporting Program (GHGRP).⁹⁵² These data represent a significant step forward in understanding GHG emissions from this sector and EPA expects that it will be an important tool for the agency and the public to analyze emissions, and to understand emission trends. EPA is using GHGRP data to update emission estimates in the GHG inventory, and we plan to continue to leverage GHGRP data to update future GHG Inventories.

The EPA-promulgated 2012 New Source Performance Standards (NSPS OOOO) will reduce emissions of ozone precursors from natural gas facilities and have methane and hazardous air pollutant reduction co-benefits. The NSPS standards require that emissions from natural gas wells that are hydraulically fractured be controlled using flaring or reduced emission completion (REC) technology from completions and workovers starting in 2012. RECs used by natural gas well drillers capture the natural gas emissions that occur during well completion, instead of venting or flaring the emissions. Starting in January 2015, RECs are required for natural gas well completions and workovers. The NSPS also regulates the emissions from certain new natural gas production equipment, including dehydrator vents and condensate tanks.

The Energy Information Administration (EIA) projects natural

gas production to increase by about 19 percent by 2025. However, as noted in the 2016 Second Biennial Report of the United States of America, EPA projects emissions of methane to increase, by only 5 percent during this timeframe; thus, methane emissions in 2025 are expected to be 12 percent lower than in 2014 per equivalent volume of natural gas being produced.

EPA is taking additional steps to reduce the emissions of methane from natural gas and oil production facilities. On May 12, 2016, EPA finalized regulations (2016 NSPS OOOOa) which, among other things, include methane standards for oil and gas equipment used across the oil and gas sources currently only regulated for VOCs, and require the use of reduced emissions completions at hydraulically fractured oil wells.⁹⁵³ In March of 2016, the U.S. EPA and Canadian Environment and Climate Change Canada (ECCC) announced plans to regulate emissions from existing oil and gas sources.^{954 955 956} The goal of these various actions is to achieve an aggregated 40 to 45 percent reduction in methane emissions relative to methane emissions in 2012. The lifecycle analysis presented here and in RIA Chapter 13 attempts to represent GHG emissions in the year 2025, but probably overestimates those emissions because the analysis does not take into account the 2016 NSPS, or any future action that would address existing sources.

In the GHG Inventory, emissions associated with powering the units or equipment (*i.e.*, compressors, pumps) used in natural gas production, processing, transmission and distribution are aggregated with all the other fossil fuel combustion activities. Rather than attempt to disaggregate those specific GHG emissions from the rest of the process emissions in the GHG Inventory, we instead used the estimated emissions for these sources provided by GREET.

(2) Downstream Emissions

Downstream emissions associated with natural gas differ between CNG

and LNG. We discuss the emissions of both types below.

(a) Compressed Natural Gas (CNG)

Natural gas used as CNG is compressed at the retail stations that sell the CNG and the fleet facilities which fuel the CNG fleet vehicles. Thus, it is typically off-loaded from the broader natural gas system where the vehicles using CNG are refueled. To get the natural gas to the CNG retail facilities, which are mostly located in or near urban areas, the natural gas is normally shipped through the distribution system downstream of the natural gas transmission system. CNG trucks are then refueled at the retail stations providing CNG. Each time a CNG refueling event occurs, a small amount of natural gas is released to the environment. We estimated the volume of CNG emitted by this equipment during refueling based on past data collected on these types of fueling fittings (described in RIA Chapter 13.1.2.1). Since CNG storage systems are designed handle very high pressures, they must be designed to have no leaks, so the CNG could remain stored in the CNG tanks indefinitely. However, should a leak occur, the very high pressure at which CNG is stored dramatically increases fugitive emissions. We do not have any data to suggest that fugitive emissions from CNG trucks and assume for this analysis that CNG fugitive emissions from CNG storage at retail/fleet facilities and by trucks is zero. However, we recognize that this clearly underestimates the methane emissions from these storage facilities since they are unlikely to be leak-free in every instance.

Stored at 3600 psi the energy density of CNG is only about 25 percent of the energy density of diesel fuel. This lower energy density is a disincentive for using CNG in long haul trucks because it limits the vehicle's range. However, as described in the Chapter 13.1.3.1 of the RIA, using an adsorbent for natural gas (ANG) could improve the energy density of CNG, which would make it a better candidate for natural gas storage for long range combination trucks.⁹⁵⁷ Or, if used to store CNG at the same density, could reduce the compression energy required to compress the CNG since it could be stored at a lower pressure.

(b) Liquefied Natural Gas (LNG)

A primary reason for liquefying natural gas is that it allows storing the natural gas at about 60 percent of the density of diesel fuel, which is more than twice as dense as CNG. For this reason, LNG is a primary fuel being considered by long haul trucks.

Liquefaction is the first step downstream of the natural gas production, processing and distribution system for making LNG available to trucks. This step involves cooling the natural gas until it undergoes a phase change from a gas to a liquid at a low pressure. LNG plants are configured differently depending on their ultimate capacity. Large LNG export facilities produce 5 million metric tons, or more, per year of LNG and the economy of scale of these large plants supports the significant addition of capital to reduce their operating costs and energy use. An LNG plant solely producing LNG for truck fuel would likely be significantly smaller (*i.e.*, 0.1 million metric tons per year) and have a poorer economy of scale than the LNG export facilities. Their energy efficiency would be expected to be much lower on a percentage basis. The California Air Resources Board estimated that the liquefaction plants used for producing truck LNG fuel are 80 percent efficient, compared to 90 percent efficient for LNG export facilities.⁹⁵⁸ In other words, the amount of energy used to liquefy the natural gas would be equivalent to the energy content 10 to 20 percent of the natural gas coming into the facility. CARB recently conducted its lifecycle assessments for LNG assuming both 90 percent efficiency value as well as 80 percent efficiency due to the uncertainty of where the LNG would be sourced from (this assessment by CARB is solely for illustrative purposes—to qualify for credit under the Low Carbon Fuel Standard (LCFS), the actual LNG plant performance would need to be the basis for any submission for requesting credit under the LCFS). For this lifecycle analysis of LNG as a truck fuel, we assume that LNG plants are 80 percent efficient, which is consistent with the types of LNG plants that would be dedicated producers of LNG for transportation purposes. We also estimated the fugitive methane emissions at the plant, as well as carbon dioxide emissions emitted by the processes which liquefy the natural gas. Because LNG plants are located separate from the retail facilities, they can be

located to access the lowest cost feedstock. This means the natural gas for LNG can be sourced from the larger natural gas transmission pipelines which are upstream of the distribution pipelines. Once the natural gas is liquefied at the liquefaction plant, it is stored in an insulated storage tank to keep the LNG liquefied.

LNG is typically transported to the retail station using insulated trailers designed specifically for transporting LNG. Boil-off emissions can occur during transport, but only if the temperature of the LNG increases to the point the pressure relief valve opens. However, since the LNG is super cooled, boil off events are likely to be rare. LNG is also stored in an insulated storage tank at the retail facility. Heat gain in the storage tank could eventually lead to boil-off emissions. Service stations with little LNG demand are at a higher risk of boil-off emissions compared to service stations which have a significant throughput volume. LNG stations could be configured to avoid boil-off events to the atmosphere, such as venting to a co-located CNG facility, venting to a nearby natural gas pipeline, or oxidizing the methane to carbon dioxide. In the absence of other information, we used CARB's estimate of boil-off emissions for LNG transportation by the tanker truck between the LNG plant and retail outlets and from LNG retail facilities.⁹⁵⁹

LNG vehicles generally refuel LNG retail outlets or fleet refueling facilities much the same as other vehicles. However, because the fuel is under pressure, when the refueling nozzle is disconnected from the LNG tank nozzle, a small amount of methane is released to the environment. We estimated the volume of LNG emitted by this equipment during refueling based on past data collected on these types of fueling fittings (described in RIA Chapter 13). In addition, operators sometimes reduce the pressure in the truck's LNG tank to speed up the refueling process, which can emit methane as well. In some cases the retail station is equipped with another hose and associated piping to vent the excess gas to the retail stations' storage tank where it would usually condense back to a liquid due to the lower temperature of that tank, or perhaps be vented to a natural gas pipeline. However, for those retail outlets without such vent lines to the storage tank, the operator may simply vent the truck's storage tank to the atmosphere. We estimated the emissions for a boil-off event or venting an LNG tank prior to refueling as part

of a sensitivity analysis for our lifecycle analysis.

(c) Comparing CNG to LNG

The differences between CNG and LNG refueling patterns are important. Only a single facility, the retail outlet, is required for distributing CNG, while LNG requires both a liquefaction plant and a retail outlet and a means for transporting the LNG from the liquefaction plant to retail. Relying on a single facility simplifies the logistics of providing CNG and reduces the opportunity for methane leakage to the environment. However, this emissions disadvantage of LNG compared to CNG is offset somewhat because LNG is expected to access natural gas from the upstream transmission system (due to lower prices), which avoids methane emissions associated with the downstream natural gas distribution system.

(d) Vehicle Emissions

There are several different ways that diesel heavy-duty engines can be configured to use natural gas as a fuel. The first is a spark ignition (Otto cycle) natural gas (SING) engine. The SING heavy duty engine burns the fuel stoichiometrically and uses a three-way catalyst, and some also add an oxidation catalyst to provide the greatest emissions reduction. In this case the engine compression ratio is reduced similar to that of a gasoline engine and thus its thermal efficiency is lower than a diesel-like engine by about 10–15 percent.

The second is a direct injection natural gas (DING), diesel cycle. The DING engine uses a small quantity of diesel fuel (pilot injection) or a glow plug as ignition sources. As the injection system for the diesel fuel does not have the capability of greater injection quantities, this option has no dual-fuel properties. On the other hand, an optimization of the pilot injection can be made to achieve lower emissions. An advanced high pressure direct injection (HPDI) fuel system combining the injection of both diesel fuel and natural gas can be used for lean burn combustion. This enables the engine to maintain the efficiency advantage of a compression ignition engine while running mainly CNG/LNG.

The third is a mixed-fuel natural gas (MFNG), diesel cycle. In a mixed-fuel engine, natural gas is mixed with intake air before induction to the cylinder and diesel fuel is used as ignition source. Mixed-fuel vehicle/engine means any vehicle/engine engineered and designed to be operated on the original fuel(s), or a mixture of two or more fuels that are

⁹⁵⁸ Detailed California-Modified GREET Pathway for Liquefied Natural Gas (LNG) from North American and Remote Natural Gas Sources, Version 1.0, California Air Resources Board, July 20, 2009.

⁹⁵⁹ Ibid.

combusted together. Engine results have shown that the efficiency of the engine could decrease by about 2–5 percent in mixed-fuel mode compared to diesel mode and that the diesel replacement was approximately 40–60 percent.

Each of these natural gas engine types has its merits. The SING engine is less costly, but is less fuel efficient and because of the lower compression ratio it has less torque than the DING and MFNG diesel cycle engines. Furthermore, the SING engine usually is designed for a shorter lifespan. The DING engine is likely the most expensive because of the special natural gas/diesel fuel injection system and large required amount of natural gas (LNG or CNG) storage since the truck must run on natural gas. However, because the truck can run almost completely on natural gas, the DING engine has the potential to more quickly pay down the higher investment cost of the natural gas truck. The MFNG engine provides the truck owner the flexibility to operate either on both natural gas and diesel fuel, or solely on diesel fuel, but at the expense of a slower natural gas investment pay down rate because at most 60 percent of the fuel it consumes can be natural gas.

Phase 1 set methane emission standards for both CNG and LNG trucks, so it is important to separate those trucks built before 2014 from those built in 2014 and later. The trucks built before 2014 only needed to meet standards for nonmethane hydrocarbon (NMHC) and other criteria pollutants, which means that the methane emissions from these trucks are unregulated. Our certification data show that the methane tailpipe emissions from these trucks/buses ranges from 2–5 g/bhp-hr for both spark ignition (gasoline type) and compression ignition (diesel type) engines.

For 2014 and later, DING and MFNG natural gas trucks or natural gas conversions of 2014 and later diesel trucks, the trucks must meet a 0.1 g/bhp-hr methane emission standard in the case of a larger truck engine tested with an engine dynamometer, and a 0.05 g/mile methane emission standard in the case of smaller trucks tested on a chassis dynamometer.⁹⁶⁰ For SING engines, the methane standards take effect in 2016.⁹⁶¹ Natural gas truck manufacturers are allowed to offset methane emissions exceeding the methane emission standard by

converting the methane emission exceedances into CO₂ equivalent emissions and using CO₂ credits. For the natural gas engine certifications that EPA received for 2014, 2015 and 2016, the truck manufacturers chose to continue to emit high levels of methane (up to 2 g/bhp-hr) and use carbon dioxide credits to offset those emissions. We do not know whether this practice will continue in the future; however, for evaluating the lifecycle impacts of natural gas heavy-duty trucks, we assume that natural gas trucks emit higher amounts of methane than the standard. It is worth noting that, because manufacturers have less experience controlling methane emissions, the potential exists for deterioration or malfunction of the engines, fuel supplies, or associated emission control devices on these trucks to occur in such a manner to result in higher methane emissions in actual use. We have not specifically accounted for the potential for increased methane emissions from high-emitter natural gas trucks.

Some amount of combustion gases typically leaks into the crankcase across the piston rings (blow-by). These crankcase emissions generally include some unburned fuel along with other combustion products, and for natural gas engines, this includes methane. The crankcase of the spark ignition engines is vented into the intake of the engines; thus, any methane that ends up in the crankcase is rerouted back to the engine where it would be combusted. For compression ignition engines, however, the crankcase emissions are allowed to be vented into the exhaust pipe downstream of the aftertreatment devices, and therefore can be released to the atmosphere, provided the manufacturer measures them and includes them in the total emissions. This means that crankcase emissions of methane count against the Phase 1 methane standard. Another potential source of methane emissions from CNG and LNG trucks is fugitive emissions from the engine and from the piping which routes the fuel to the engine. Thus, either while parked or operated, this part of the vehicle fuel and engine systems could leak methane to the environment (which is different from boil-off emissions from LNG trucks discussed below). We do not have data nor did we develop an estimate for these potential fugitive emissions from these types of in-use leaks. If the natural gas vehicles are well maintained, these emissions are likely to be very low.

The thermal efficiency (the ratio of energy converted to work versus energy consumed) of the natural gas engine also

plays a role in the lifecycle emissions of the truck. Natural gas engines are generally less efficient than their gasoline and diesel counterparts. Furthermore, manufacturers often choose to produce spark-ignition stoichiometric natural gas engines for use in diesel applications. Spark-ignition natural gas engines can be as much as 15 percent less efficient than compressed ignition engines which operate on diesel fuel. In our lifecycle analysis, we provide two different sensitivities for natural gas vehicles assuming that they are 5 percent and 15 percent less efficient.

An important difference between CNG and LNG is the way in which the fuels are stored on the vehicle. The CNG is contained in a permanently sealed system while the LNG system is potentially open to the environment (depending on operating patterns). Provided that there are no leaks in the storage system, the CNG truck is inherently low (zero) emitting with respect to evaporative emission and a parked truck would contain the CNG indefinitely. However, this is not so for LNG trucks, which would have very high emissions if the truck were to be parked so long that its entire contents would boil off and be emitted to the environment. Methane venting emissions mean loss of fuel for the operator, which creates a disincentive to allow the fuel to warm to the point of venting. Nevertheless, even occasional venting events can have significant impacts. Thus, EPA remains concerned about boil-off emissions from LNG truck fuel storage systems. When the liquefied natural gas is pumped into the truck LNG tanks, it is “supercooled,” meaning that the pressure of the LNG is well below the pressure at which the natural gas vent valve would relieve the LNG pressure. If the truck is driven extensively, the drawdown of liquid level will reduce the pressure in the storage tank which will cause some of the fuel to boil off and the heat of vaporization would thus cool the rest of the liquid in the LNG storage tank. It is possible that the fuel would maintain its supercooled temperature, or possibly even cool further below its supercooled temperature, the entire time until the LNG is completely consumed.

Unless the truck is driven enough to consume the LNG fuel while it is still at the very low-temperature and low-pressure, it will warm due to the ambient temperature gradient through the tank wall, and vaporize, causing the temperature and pressure of the LNG to rise. When the pressure reaches a maximum of 230 psi a safety release valve releases the methane gas to vent

⁹⁶⁰ An exception is that small volume, heavy-duty natural gas truck manufacturers are exempt from EPA's GHG regulations.

⁹⁶¹ See 76 FR 57192, 40 CFR 1036.108(a)(2) and 1037.104(c) (which is proposed to be redesignated as 40 CFR 86.189–14(k)(5)).

excess pressure. There are two industry standards used to design tanks to reduce the temperature increase, one for a 3-day hold time⁹⁶² and one for a 5-day hold time.⁹⁶³ Hold time is the time elapsed between the LNG refueling and venting.

A large amount of methane can be released with each boil-off event. If aware of the impending boil-off, such as when the truck is being maintained, the truck driver could hook up the LNG tank to a hose which would vent the natural gas emissions to a CNG system which could reuse the boil-off natural gas as CNG, or vent the natural gas emission to a natural gas pipeline. Otherwise the boil-off emission would simply vent to the atmosphere. If the truck had 200 gallons of LNG storage capacity, the estimated quantity of boil-off emissions would range from 3 to 9 gallons of LNG for each boil-off event depending on the fill level of the LNG tank, assuming that the boil-off event results in a drop of pressure in the LNG tank from 230 psi to 170 psi. Each boil-off event has the potential to release on the order of 5,300–15,800 grams of CH₄ which equates to 132–400 kilograms of CO₂-equivalent emissions, using a methane global warming potential (GWP) of 25 (assessed over 100 years).⁹⁶⁴ If the vehicle continues to sit for five more days and boil-off events occur each day to several times per day as the tank vents and rebuilds in pressure, the sum total of the boil-off events can result in over a million grams of CO₂-equivalent emissions.

(3) Results of Lifecycle Analysis

To estimate the lifecycle impact of natural gas used by heavy-duty trucks, we totaled the estimated CO₂, CH₄, N₂O emissions for the upstream and downstream portions of the natural gas system. The methane and nitrous oxide emissions are converted to carbon dioxide-equivalent emissions using the appropriate GWP conversion factors. The GWP conversion factors EPA currently uses in this analysis are for a 100-year timeframe, are 25 and 298 for methane and nitrous oxide, respectively.⁹⁶⁵

To establish the impacts of natural gas use in the heavy-duty fleet, it was

necessary to compare the lifecycle impacts of natural gas against the base fuel it is replacing, which generally is diesel fuel. The lifecycle impact of diesel fuel was estimated by the 2015 GREET model for the current production and use of diesel fuel. In 2015, the National Energy Technology Laboratory (NETL) updated its diesel fuel lifecycle analysis to assess diesel fuel use by trucks in the year 2014.⁹⁶⁶ The revised analysis shows much higher upstream emissions compared to GREET, but much lower truck GHG emission compared to GREET, and on balance is slightly lower than GREET. Thus, if we used the NETL lifecycle analysis, on a relative basis, natural gas trucks would appear slightly higher emitting than diesel engines.

To illustrate the relative full lifecycle impact of natural gas-fueled heavy-duty vehicles compared to diesel fueled heavy-duty vehicles, we assessed two different scenarios. The first is a conversion of a 2014 or later diesel engine to use CNG. Of the tens of thousands of heavy-duty natural gas trucks currently in use, most are of this type. It is likely that nearly all CNG conversions being done in 2021 and later will be for vehicles subject to the 2014 and 2016 methane emissions standards. Thus, for this analysis we assume that all converted natural gas trucks will need to comply with the methane standards. The methane standard requires heavy-duty trucks to comply with a 0.1 g/bhp-hr or a 0.05 g/mile methane tailpipe standard. Based on certification data for post-2014 CNG trucks, the trucks emit from 0.7 to 2 g/bhp-hr methane and thus require the use of CO₂ emission credits to show compliance with the methane standard. For the purposes of this review, we assume that these trucks emit 1 gram of methane per brake horsepower hour. We provide two sensitivities to capture the lower thermal efficiencies of natural gas trucks: 5 percent less thermally efficient (thermal high) which is representative of a diesel cycle engine and 15 percent less energy efficient (thermal low, which is 10 percent worse thermal efficiency than the 5 percent less thermally efficient case) which is

representative of a gasoline cycle engine.

The second scenario we assessed is a combination LNG tractor trailer (LNG is most common with tractors because it provides a greater range of operation). While the fuel storage in this case is LNG (as opposed to CNG in the case above), the engine options are similar to the above case (diesel and gasoline cycle as represented by the thermal efficiency sensitivities). Also similar to the CNG case, we assume that these engines continue to emit 1 gram per brake-horsepower-hour of methane despite being subjected to either the 0.1 gram per brake horsepower-hour or the 0.05 gram per mile methane emission standard. We make two different assumptions with respect to refueling and boil off emissions. In the LNG average case, we assume a modest quantity of refueling and boil-off methane emissions as estimated by GREET. The second boil-off emission estimate is a sensitivity analysis which assumes that the LNG storage tank is either vented to the atmosphere each time the driver refills his tank, or that there is a boil-off event for each LNG tank filling. As discussed above, we do not expect such high refueling and boil-off emissions to be common practices for newer trucks that are operated regularly. However, as the use of these trucks decreases as they age and are sold into the secondary market, the risk for refueling and boil-off emission events increases—this estimate provides a simple sensitivity emission estimate. The relative lifecycle analysis is shown in Figure XI–1.

A third comparison made in Figure XI–1 is the relative tailpipe-only emissions for diesel and natural gas trucks. The quantity of carbon dioxide, methane and nitrous oxide emissions from a diesel truck is from GREET. The carbon dioxide emissions from a natural gas-fueled truck is calculated and is based on the carbon-hydrogen content of methane. The methane emissions from a natural gas-fueled truck is based on natural gas truck certification data (and so does not include any methane emissions from the natural gas storage tanks onboard the truck nor other fugitive emissions).

⁹⁶⁴ See Section XI.D.(2)(a) for a discussion of different values for the GWP of methane.

⁹⁶⁵ These global warming potential values are based on the Fourth Assessment Report authored by the Intergovernmental Panel on Climate Change.

⁹⁶⁶ Cooney, Greg of Booz Allen Hamilton; Approaches to Developing a Cradle-to-Grave Lifecycle Analysis of Conventional Petroleum Fuels Produced in the U.S. with an Outlook to 2040; for the National Energy Technology Laboratory (NETL), October 6, 2015.

Figure XI-1 Full Lifecycle Analyses (except tailpipe only emissions) of Diesel, CNG and LNG Trucks (Projected Upstream Methane Emissions in 2025, methane GWP of 25)

The first two bars of Figure XI–1 show that based solely on tailpipe emissions (with thermal efficiency adjustments and assuming 1 g/bhp-hr methane emissions at the truck), CNG trucks are estimated to emit about 10 percent less GHG emissions than diesel engines if the engine is only 5 percent less efficient than a diesel engine, and about the same GHG emissions if the engine is 15 percent less efficient than a diesel engine. The four full lifecycle analyses represented by the right four bars in the figure show that CNG trucks are estimated to emit less GHG emissions than diesel trucks, although if their thermal efficiency is much lower (15 percent less than the diesel fueled engine) their GHG emissions would decrease to 5 percent lower than diesel trucks.

Figure XI–1 also shows that LNG trucks with an average extent of boil-off emissions can have about the same greenhouse gas footprint as diesel trucks, provided the engines' energy efficiency is only 5 percent lower than diesels. However, if the LNG engine is 15 percent less energy efficient than the diesel fuel engine, the GHG emissions of the LNG truck would be higher. In addition, an LNG truck with refueling or high boil-off emissions, would emit about one third more GHG emissions than diesel fuel trucks. From a lifecycle perspective, LNG trucks appear higher emitting than CNG trucks largely because of the low thermal efficiency of

the small liquefaction facilities. If a fleet of LNG trucks were to access LNG from a large, LNG export facility, which are much more energy efficient than the smaller liquefaction facilities, the relative lifecycle impacts of the LNG trucks would be much better.

It is important to point out the uncertainties associated with the lifecycle estimates provided in the above figures. As discussed above, there is uncertainty in both the upstream and downstream methane emission estimates for natural gas facilities and equipment, and the trucks that consume natural gas. There is also uncertainty in the diesel fuel lifecycle analysis conducted by GREET and NETL. Finally, the lifecycle analysis is sensitive to the GWP factor used to assess methane and nitrous oxide, and if a different GWP value were to be used, it would affect the relative lifecycle impact of natural gas relative to diesel in heavy-duty trucks (see Chapter 13.1.4 of the RIA for sensitivity analyses regarding upstream methane emissions and the use of different GWP factors).

We compared our lifecycle emission estimates for natural gas, relative to diesel fuel, with the estimates provided by the California Air Resources Board (CARB) for its Low Carbon Fuel Standard (LCFS). For our emissions estimate used in the comparison we used the carbon dioxide-equivalent (CO₂eq) emissions estimated for 2014 and later engines, which must comply with a methane tailpipe emissions

standard, and assumed that the engine was 5 percent less thermally efficient than a comparable diesel engine. Both analyses used GWPs based on 100 year timescale (*i.e.*, a GWP of 25 for methane and 298 for nitrous oxide).⁹⁶⁷ For the CARB emissions estimates, we used the estimates made for what CARB terms "illustrative purposes" using the values printed in the April 3, 2015 workshop handouts.⁹⁶⁸ CARB estimates that CNG engines emit 86 percent of the CO₂eq emissions as a diesel truck using the EER-adjusted values which reflects 11 percent lower energy efficiency than a diesel truck. When we adjust our analysis to reflect a truck which is 11 percent less efficient than a diesel truck, our analysis estimates that CNG engines emit 89 percent of the CO₂eq emissions as a diesel truck. An important reason why CARB estimates lower CNG truck GHG emissions than our analysis is that a much larger portion of the electricity used to compress natural gas is renewable in California than the rest of the country. Also, our analysis accounts for the recent improvements in the GHG Inventory which shows higher natural gas upstream emissions. Using the same assumption that natural gas trucks are 11 percent less efficiently, CARB estimates LNG engines emit about 94

⁹⁶⁷ See Section XI.D.(2)(a) for a discussion of different values for the GWP of methane.

⁹⁶⁸ CA–GREET 1.8b versus 2.0 CI Comparison Table, LCFS Workshop Handout, California Air Resources Board, April 3, 2015.

percent of the CO₂eq emissions. After adjusting our analysis to also assume that trucks are 11 percent less efficient, our natural gas lifecycle analysis estimates LNG trucks emit 106 percent of the CO₂eq emissions as a diesel truck. The reasons why are LNG truck emission are so much higher than CARB's is because we assume that LNG liquefaction plants are only 80 percent efficient as opposed to CARB's assumption that LNG liquefaction plants are 90 percent efficient. Also CARB assumes no boil-off or venting emissions from LNG trucks and for this comparison, we used our more modest boil-off and venting assumption, as described above. Overall, our estimates seem to be consistent to those estimated by CARB when we account for the different assumptions used in the respective analyses.

The lifecycle analysis at proposal comparing the GHG impacts of natural gas versus diesel fuel use by heavy-duty trucks did receive some comments. Probably the most prevalent comment is that EPA was underestimating methane emissions from the upstream natural gas sector. As noted above, the analysis for this final rule increased the estimate of methane emissions from the upstream natural gas sector by about one third. Other comments suggested that the Agencies should find emissions data or estimate methane emissions from the potential methane emission points for which there was no data to make such an estimate in our lifecycle analysis. The final rule natural gas lifecycle analysis does make methane emission estimates at some of those likely methane emission points for which we did not have data, nor make any estimates. Some commenters stated that the natural gas lifecycle analysis should be dropped because a similar lifecycle analysis was not conducted for other alternative fuels. The agencies chose to do a natural gas lifecycle analysis because of some of the projections for a rapid transition of heavy-duty trucks to natural gas, and because of methane's potency as a greenhouse gas. Other comments are presented and discussed in Section 12.3 of the RTC.

C. Projected Use of LNG and CNG

We reviewed several sources to estimate how much natural gas is currently being used and is projected to be used by heavy-duty trucks. Projections for this emerging technology range from 7 percent of new heavy-duty vehicle sales to over 40 percent by 2040. Large uncertainties exist even since the

2014 NAS First Report was written.⁹⁶⁹ We believe the EIA projections are the most credible for capturing recent trends, and for projecting future natural gas use by heavy-duty trucks. There are several factors that support this assessment.

First, in its 2014 Annual Energy Outlook (AEO), EIA estimates that natural gas fueled 0.4 percent of the energy use of heavy-duty trucks in 2014. This estimate is consistent with the fraction of the heavy-duty fleet which is fueled by natural gas as estimated by the industry.⁹⁷⁰

Second, the EIA projection is based on an economic analysis which considers the increased cost of manufacturing a natural gas truck over a diesel truck, the fuel savings for using natural gas instead of diesel fuel, and whether the payback time of the fuel savings against the increased truck cost would result in purchases of natural gas trucks. As part of this analysis, EIA assumes that lighter heavy-duty trucks would use CNG, which is a lower cost technology suited for the shorter driving distances for these trucks. The long haul trucks, however, require larger on-board stores of fuel to extend the driving range which is satisfied by storing the natural gas as a liquid. As noted earlier, LNG has about 60 percent of the energy density of diesel fuel, compared to CNG which has only 25 percent of the energy density of diesel fuel. To satisfy the long driving range of the long haul trucks, EIA assumed that they would use LNG rather than CNG. The assumptions used by EIA for conducting its economic analysis are reasonable.

Third, EIA is one of the several organizations in the world which collects fuel pricing data and projects future fuel prices using a sophisticated modeling platform. One of the most important assumptions in projecting the future use of natural gas in the transportation sector is the relative price of natural gas to the price of diesel fuel. Thus, we started with the EIA methodology and updated the diesel and natural gas prices in our analysis using the most recent AEO projections.

In 2015, the price of natural gas purchased by industrial users was less than \$5 per million BTU. The price of crude oil has been volatile during 2015 as the Brent crude oil price started at about \$50 per barrel, but decreased to under \$30 per barrel, but now (Spring

2016) seems to be selling in the range of \$30 to \$40 dollars per barrel. EIA reported the average retail diesel fuel price in 2015 was about \$2.70 cents per gallon.⁹⁷¹ When comparing the natural gas spot market price on a diesel equivalent basis to the diesel fuel price, it appears that natural gas is priced about one quarter of the diesel fuel price. However, if used as compressed natural gas, the natural gas must be distributed through smaller distribution pipeline system that exists in cities, which increases the price of the natural gas. Then the natural gas must be compressed and stored at a retail outlet, and then dispensed to CNG trucks. The estimated retail price of CNG is \$2.29 on a diesel gallon equivalent (DGE) basis, or about \$0.41 DGE less than diesel fuel. LNG plants are assumed to be located close to large transmission pipelines away from cities, thus, it is sourced from lower cost natural gas. However, for producing LNG, the natural gas must be liquefied, shipped to retail outlets, stored and then dispensed to LNG trucks. These steps add substantially to the price of the LNG and the estimated retail price of LNG is \$2.71 DGE, or about the same as diesel fuel.

In its 2015 AEO projections, EIA estimates that crude oil prices in the upcoming years will increase slightly and are projected to reach \$140/bbl in 2040. Natural gas prices are also expected to increase only slightly over this period.

Fifth, the assumptions regarding payback used by EIA seemed reasonable. EIA projects that natural gas trucks begin to be purchased when the payback times are 4 years or less based on a survey conducted by the American Trucking Association. The 2014 NAS Phase 2 First Report cites the payback for the extra cost of natural gas trucks as 2 years, but other sources report a longer return closer to 4 years.⁹⁷²

For many fleets, the perceived payback times are too long to be interested in purchasing natural gas trucks without subsidies to compensate for the higher purchase price. According to EIA data, half the natural gas consumption by cars and trucks is in California, a state that subsidizes the purchase price of natural gas vehicles, and also subsidizes the cost of natural gas dispensing stations. The Low Carbon Fuel Standard in place in California also incentivizes natural gas use because natural gas is considered to

⁹⁶⁹ B. Tita, *Slow Going for Natural-Gas Powered Trucks*; Wall Street Journal, 8/26/2014.

⁹⁷⁰ NGV America estimates that there are 62,000 natural gas fueled heavy-duty trucks and buses operating in the U.S. out of a total of 17.5 million heavy-duty trucks and buses operating in the U.S., which equates to 0.4%.

⁹⁷¹ Weekly Retail Gasoline and Diesel Prices (Including Taxes), EIA, www.eia.gov/dnav/pet/pet_pri_gnd_dcus_nus_a.htm.

⁹⁷² Early LNG Adopters Experience Mixed Results; Truck News, October 1, 2013.

cause less of an impact on the climate than petroleum-based gasoline and diesel fuel.⁹⁷³ The majority of the other half of the NG fleet resides in states which also subsidize the cost of motor vehicles using natural gas.

Based on the EIA projections for crude oil and natural gas prices, the payback time of LNG trucks is expected to remain relatively long until sometime after 2030 when crude oil prices are projected to begin increasing and the diesel fuel price increases above \$4 per gallon. Thus, natural gas use by heavy-duty trucks is not projected by EIA to increase above 1 percent of the heavy-duty fuel demand until after 2030.

Even when the apparent payback time for CNG and LNG trucks use is favorable to fleet owners, low fuel availability could still slow the transition to CNG and LNG. This is because CNG and LNG availability at service stations is currently 1 percent or less of the availability of gasoline and diesel fuel and therefore not available for most fleets. LNG availability is particularly challenging because in addition to an LNG service station, an LNG liquefaction plant would be needed as well.

If the number of natural gas truck sales remains a small portion of the heavy-duty truck fleet, even if natural gas trucks emit either higher or lower greenhouse gas emissions than diesel fuel trucks, there would be little impact on overall greenhouse gas emissions. The low natural gas use by the heavy-duty sector during the Phase 2 timeframe will give us time to learn more about both upstream and downstream methane emissions to gain a better understanding of the lifecycle impacts of natural gas use by heavy-duty trucks. It will allow EPA more time to consider and put into place the best additional steps to further reduce upstream and downstream methane emissions which will improve the lifecycle impacts of natural gas use by heavy-duty trucks should the heavy-duty truck fleet begin consuming natural gas in much larger quantities.

D. Natural Gas Emission Control Measures

Although natural gas vehicles are already subject to evaporative emission standards, the increasing interest in using natural gas as a heavy-duty fuel has led industry to further investigate

how to improve the overall emission performance of natural gas vehicles, especially with respect to reducing methane leaks.

(1) Control Measures

As described in Section XII.A.3, EPA is adopting a 5 day hold time requirement for LNG fuel tanks to reduce venting emissions.

As described in Section II., EPA is not adopting the proposed changes related to crankcase emission control from natural gas engines.

(2) Additional Natural Gas Requirements and Discussion

The discussion below includes new and revised natural gas program requirements being finalized. It also address other topics for with the agencies are not taking any action at this time. We will continue to monitor the market growth of these vehicles and we plan to review the greenhouse gas emissions impacts at a future date when natural gas vehicles comprise a larger percentage of the overall heavy duty fleet.

(a) Changing Global Warming Potential Values in the Credit Program for CH₄ (see also Preamble Section II.(D)(5)(b))

The Phase 1 GHG rule included a compliance alternative allowing heavy-duty manufacturers and conversion companies to comply with the respective methane or nitrous oxide standards by means of over-complying with CO₂ standards (40 CFR 85.525). More specially, EPA allows manufacturers to use CO₂ credits (generated from the same averaging set) to comply with the methane and nitrous oxide requirements after adjusting the CO₂ emission credits based on the relative GHG equivalents. To establish the GHG equivalents used by the CO₂ credits program, the Phase 1 heavy-duty vehicle rulemaking incorporated the IPCC Fourth Assessment Report GWP values of 25 for CH₄ and 298 for N₂O, which are assessed over a 100 year lifetime. EPA is largely continuing this allowance for Phase 2.

Since the Phase 1 rule was finalized, a new IPCC report has been released with new GWP estimates. EPA asked for comment on whether the methane GWP used to establish the GHG equivalency value for the CO₂ Credit program should be updated to those established by IPCC in its Fifth Assessment Report (AR5). The IPCC AR5 presents four different potential values for the GWP of methane over a 100 year lifetime, ranging from 28 to 36. These values are the result of slightly different calculation methods. Therefore, we not only requested

comment on whether to update the GWP for methane to that of the AR5, but also on which value to use from this report. The GWPs of 28 and 30 are both a result of using a carbon cycle approach consistent with that used in the Fourth Assessment Report. This carbon cycle approach included a climate-carbon feedback when calculating the lifetime of a pulse of carbon dioxide emissions, but did not include any climate-carbon feedback when calculating the impacts of a pulse of non-CO₂ greenhouse gas emissions. As the GWP is the ratio of the impact of a pulse of non-CO₂ GHG emissions relative to a pulse of carbon dioxide emissions, a second approach was presented where the non-CO₂ GHG pulse also included climate-carbon feedbacks. This second approach yields GWP values of 34 or 36. For the purposes of this rule, EPA is choosing the approach that includes climate-carbon feedbacks for both non-CO₂ and CO₂ pulses, as the agency considers this the approach most likely to be adopted by the international scientific community in future assessments on the timescale of this rule. The IPCC presents the value of 34 as the default value for the methane GWP, but also reports a value of 36 for "fossil" methane to take into account the atmospheric CO₂ that would result from the oxidation of methane in the atmosphere.

We received a number of comments on this issue. For the most part, the environmental community favored using the more recent GWP value and even some commented that EPA should use a methane GWP based on a 20 year timeframe. On the other hand, the natural gas industry and natural gas truck manufacturers commented that EPA should not update to the newer GWP values but continue to use the methane GWP value from the AR4 IPCC report because EPA is still using the methane GWP from the AR4 today in other contexts. Although EPA is currently using AR4 values in other contexts, it is unlikely that EPA will still be using AR4 values in 2021 when the Phase 2 requirements begin. Thus, comments opposing the use the methane GWP from the later IPCC report are not persuasive. EPA will continue to base the credit adjustment on a 100 year timescale because it seems to best balance short-term versus long-term effects of climate change.

Of the possible 100 year methane GWP values presented in the IPCC AR5 report, EPA is choosing to use the value of 34 because it is the primary value presented by the IPCC and because the approach of not accounting for the CO₂ oxidation product within the GWP for

⁹⁷³ CARB currently estimates for the LCFS that CNG and LNG trucks reduce GHG-equivalent emissions by 32% and 17%, respectively, compared to gasoline and diesel fuel. In August 2014, CARB proposed reducing the GHG-equivalent benefit of CNG and LNG trucks to 22% and 3%, respectively, compared to gasoline and diesel fuel.

methane is consistent with prior IPCC practice.⁹⁷⁴ The use of this GWP for credit adjustments will not begin until 2021, when the Phase 2 engine standards go into effect. The choice of this GWP value for future rules on this timescale does not prejudice the choice of other GWP values for use in regulations and other purposes in the near term.

To be consistent with other lifecycle analyses, the agencies are continuing to use AR4 value of 25 for the methane GWP in our lifecycle analyses. However, as discussed in Chapter 13.1 of the RIA, we have also conducted sensitivity analyses using methane GWP values ranging from 7.6 to 72.

(b) Appropriate Deterioration Factors for NG Tailpipe Emissions

EPA requested comment on the current assigned deterioration factors for CO₂, N₂O, and CH₄ based on diesel technology. We received one comment on this topic indicating the commenter knew of no data to support a deterioration analysis and that our approach for deterioration should remain as is. EPA has decided not to take action on this topic at this time and will continue the Phase 1 approach.

(c) LNG Vehicle Boil-Off Warning System

EPA requested comment on the feasibility and appropriateness of a regulatory requirement that LNG fueled vehicles include a warning system that would notify the driver of a pending boil-off event as one means reduce the frequency of such events and thus limit the release of methane. We received several comments expressing safety concern related to this approach. While such a system could be beneficial to the owner of a vehicle, EPA is not taking action at this time. We encourage innovation for safe technologies to evolve for warning of potential boil-off events which would also save the vehicle owner the cost of the fuel in the tank while protecting the atmosphere from large amounts of methane gas.

(d) Extending the 5-Day Hold Time for LNG Vehicles

EPA proposed to require manufacturers to comply with the existing evaporative emission standards by showing compliance with a 5-day hold time. 80 FR 40510. We also solicited comment on the ability of emerging technologies to address an extension of 5-day requirement to a

longer period of time such as 10 days. After considering the comments, EPA is not extending the hold time beyond 5 days in this rule.

The specifications of the 5-Day Hold Time SAE J2343 safety related standard will only affect LNG vehicles starting in the year 2021 to help prevent boil-off events. After speaking to LNG truck manufacturers and LNG fuel providers, our understanding is that most LNG is dispensed at about 100 to 120 pounds per square inch gauge (psig), which corresponds to – 200 degrees Fahrenheit) and at that temperature, new LNG trucks with new LNG storage tanks are achieving more than a 5-day hold time today. However, over time, the vacuum insulation of the LNG storage tank can fail, resulting in degraded LNG hold-time as the truck ages. The requirement that the LNG truck must meet the 5-day hold-time over its entire useful life will likely improve the truck's hold time after the first several years in service. While LNG tank manufacturers are further developing their technologies for improvement of hold times and reducing boil-off from LNG storage tanks on trucks, the 5-day hold time requirement over the truck's useful life will ensure that they make the improvements to the period of the truck's life which is most at risk for boil-off events, which is when the truck is sold off into the secondary market and its use diminishes.

EPA considered requiring new trucks to have the capability to use cold fuel. Most of the LNG trucks on the road at this time use the warmer fuel; therefore, most refueling stations are dispensing the warmer fuel only. A cold fuel requirement could force refueling stations to make a large potentially burdensome investment to provide the colder fuel in addition to the warmer fuel, because only a few cold fuel LNG trucks might be sold in that area. We would need to study the implications of this scenario further and gain a better understanding of the emissions from boil-off events before we would feel confident in how a cold LNG fuel requirement would affect the refueling industry and reduce methane emissions. A cold LNG fuel requirement would likely be more feasible for new fleets since they could design their truck fleet and their own fueling equipment from the ground up to use the cold LNG fuel.

Another possible approach would be to increase the R-value of the tank to keep the warm fuel colder for longer. This likely would further reduce boil-off events, although, again, we are uncertain of the benefits versus the costs. We believe that ensuring that the

5-day hold time can be met over the truck's useful life is the best, lowest cost strategy to reduce the number of boil-off events.

(e) Capturing and/or Converting Methane Refueling or Boil-Off Emissions

Although we are not requiring it, EPA is interested in watching the progression of innovative technologies that can capture methane emissions during a boil-off event to prevent large amounts of greenhouse gas emissions into the atmosphere. We encourage design and development of ideas such as a methane canister using adsorbents such as ANG⁹⁷⁵ (adsorbed natural gas) which could be added to capture the methane which otherwise will be released to the environment during a refueling or boil-off event. Once captured, steps could be taken to route the methane to the engine intake once the vehicle is operating again, or to take steps to converting the methane to less GHG-potent CO₂.

Instead of discharging methane to the environment, the methane potentially could be burned to CO₂ using a burner. Another potential option would be to convert the methane capture in a canister to CO₂ over a catalyst.

(f) Reducing Refueling Emissions

When refueling a natural gas vehicle, some amount of methane is vented to the atmosphere. Requirements adopted as part of the Tier 3 rules require use of the ANSI-NGV1-2006 standard practice to meet the evaporative emissions refueling requirement.⁹⁷⁶ Small emissions of up to 200 cc/hr (which equates to 72 grams of methane per hour) of leakage are allowed with these tests. Often there is a vent line which carries these emissions away from the nozzle interface for safety reasons, which emissions are then vented to the atmosphere. EPA requested comment on ways to eliminate or reduce these losses. There was a mixed response on whether methane gas can be captured during refueling using systems that route methane emissions back to the fuel storage tank, whether it is a CNG tank, a CNG pipeline or re-liquefying system for LNG. Some refueling stations are already doing this as common practice.

For LNG, in addition to the boil-off issue, there is the issue of the recurrence of manual venting at refueling by truck operators. Under high pressure

⁹⁷⁵ Menon, V.C., Komarneni, S. "Porous Adsorbents from Vehicular natural Gas Storage: A Review," *Journal of Porous Materials* 5, 43–58 (1998).

⁹⁷⁶ Control of Air Pollution from Motor Vehicles Tier 3 Motor Vehicle Emission and Fuel Standards, Final Rule April 28, 2014, CFR 86.1(c) (1).

⁹⁷⁴ The corresponding N₂O value from the AR5 report is 298, which is the same as the value used in Phase 1.

circumstances, such as when the vehicle has been sitting for some time period in warmer temperatures, it is necessary to decrease the pressure in the fuel tank before new fuel can enter the tank. The recommended practice is to transfer the extra vaporized fuel to the gas station or natural gas pipeline, but this can take extra time. In some areas it has turned into common practice to just vent to the atmosphere to keep the down time at the refueling station to a minimum. In other areas there is an incentive to reroute the gas into the station storage tank or natural gas pipeline with credit towards the fuel purchase. Since this is a stationary source issue, EPA is not taking action at this time on these issues in this engine/vehicle rulemaking. We also do not have enough information on the extent of emissions and rate of occurrence for this problem.

(g) On-Board Monitoring Requirements for Boil-Off Events and Venting at Refueling

Onboard diagnostics for engines used in vehicle applications greater than 14,000 lbs GVWR are already required to detect and warn the operator when methane leaks occur due to wear of connections and components of the CNG or LNG fuel system (74 FR 8310, February 24, 2009). We requested comments on requiring on-board monitoring to track boil-off events, as well as comment on whether the excess vapors were properly vented to the station storage tanks or NG pipeline or whether the gaseous methane emissions were vented to atmosphere during refueling events. 80 FR 40512. Each boil off event has the potential to release on the order of 5,300–15,800 grams of CH₄ which translates to 132K–400K grams CO₂ equivalent with a GWP of 25 for 100 years (see RIA Chapter 13 for more information on LNG boil-off emissions calculations). EPA is not able to take further action on OBD requirements at this time since we do not have enough information on the emissions from leaks and their rate of occurrence. Designing an OBD system is complicated and expensive if we are to expect any degree of accuracy for more than just very large leaks. In CNG there is an odorant and a truck operator could potentially detect a leak if it is large enough. Even if the leak could be detected from the odor, it would be difficult to know how much is actually being released if you can smell it. Different operators will have different degrees of sensitivity with their olfactory awareness. LNG does not have an odorant and could benefit from an OBD system even more. We do, therefore, encourage the development of systems for indicating these events to

vehicle owners to both save on fuel and protect the environment.

(h) Separate Standards for Natural Gas Vehicles

As described above, the climate impact of leaks and other methane emissions that occur upstream of the vehicle can potentially be large enough to more than offset the CO₂ benefit of natural gas vehicles as measured at the vehicle tailpipe. As described earlier, EPA has taken some actions, and is considering further separate actions to control these upstream emissions. We also have some concern that the impact of upstream and downstream emissions for natural gas could be much higher than for gasoline or diesel fuel because of the high Global Warming Potential (GWP) for methane that makes even small leaks of natural gas a concern. In this way, natural gas is very different than other alternative fuels. While we are not adopting any provisions to address this here, we may consider adopting such provisions in a future rule. As discussed in Section XI.B, EPA is putting in place a series of regulations in the natural gas sector for upstream leaks. With the currently available data the uncertainties are very high in calculating upstream emissions for both natural gas and diesel vehicles. These uncertainties, the desirability of a unified national program for HD GHG and fuel consumption standards, combined with the low sales volumes projected for natural gas vehicles for the foreseeable future make it inadvisable for us to pursue more than a vehicle based standard at this time. See also Section I.F.(3) for additional discussion of why EPA is setting tailpipe standards in this rulemaking.

E. Dimethyl Ether

Although NAS (2014) focused its recommendations on natural gas, it also discussed dimethyl ether (DME), which is a potential heavy-duty truck fuel sourced from natural gas. Dimethyl ether has a high cetane number (more than 55), although its energy density is about 60 percent of that of diesel fuel. Dimethyl ether is a volatile fuel, like liquefied petroleum gas that can be stored as a liquid at normal ambient temperatures under moderate pressure. Typical DME fuel tanks would be designed to prevent any significant evaporative emissions.

A DME fueled truck is only modestly more expensive than a diesel fuel truck. The fuel tank is more expensive than a diesel fuel tank, but much less expensive than an LNG tank since it does not need to be heavily insulated. The engine modifications to enable

using DME are also modest. Because DME does not have carbon-carbon bonds that form particulate matter particles during combustion, the particulate filter, which is standard equipment on new diesel trucks, can be eliminated. This offsets some of the engine and fuel tank costs.

Although DME is sourced from cheap natural gas, the conversion of natural gas to DME and moving the fuel to retail outlets greatly increases the cost of the fuel. Based on the crude oil and natural gas prices in early 2014 (about \$100 per barrel), DME is more expensive than LNG, but still lower in cost than diesel fuel (DME is estimated to cost \$3.50/DGE, or \$0.30 DGE less than diesel fuel.) After the decline in crude oil prices, DME is estimated to be priced higher than diesel fuel.

Because there is very little DME use in the U.S. (there is only a very small fleet of trucks in California), we did not conduct a lifecycle assessment of DME, but note here a few aspects of a lifecycle analysis for DME. First, since DME is sourced from natural gas, the upstream methane emissions from the natural gas industry would still be allocated to DME. Second, there are no venting issues associated with DME as there are with LNG refueling or boil-off. Third, because DME has a lifetime of less than a week in the atmosphere, it has little direct climate impacts. Thus, it is likely that DME would have a lower GHG impact than LNG trucks, and perhaps lower than CNG trucks, although we would have to study DME use in trucks further to be more certain.

XII. Amendments to Phase 1 Standards

The agencies are revising the regulatory text specifying test procedures and compliance provisions used for Phase 1. For the most part, these amendments apply exclusively to the Phase 2 rules. In a few limited instances, the agencies are adopting changes to the Phase 1 program. These limited changes to the Phase 1 program are largely conforming amendments, and are described below, along with other minor changes to the Phase 1 compliance program. These changes generally continue to apply under the Phase 2 program.

For the convenience of the reader, we are republishing 40 CFR parts 1036 and 1037 in their entirety, including text that is not being amended. We are also republishing Phase 1 text in 40 CFR part 86. We note, however, that we have not reconsidered, rethought, or reopened the Phase 1 rules in a general sense. We have also not reconsidered, rethought, or reopened the stringency of the Phase 1 standards or other fundamental

aspects of the Phase 1 program that remain unchanged substantively.

The agencies received very few comments of these changes. Daimler commented that the agencies should not make any changes to Phase 1 because manufacturers have already developed systems to comply with the existing requirements. We do not necessarily agree that would be a sufficient reason to keep us from amending Phase 1 requirements through notice and comment rulemaking. Nevertheless, we note that we are not finalizing changes that would have any significant impact on the manufacturers' Phase 1 compliance structures.

A. EPA Amendments

(1) Pickups and Vans

EPA is relocating the GHG standards and other regulatory provisions for chassis-certified HD pickups and vans in the Code of Federal Regulations from 40 CFR 1037.104 to 40 CFR 86.1819–14. Accordingly, NHTSA is modifying any of EPA's references in 49 CFR parts 523 and 535 to accommodate the migration. EPA is making this change largely to address ambiguities regarding the application of additional provisions from 40 CFR part 86, subpart S, for these vehicles. The approach in 40 CFR 1037.104 was to state that all of 40 CFR part 86, subpart S, applies except as specified in 40 CFR 1037.104; however, the recent standards adopted for light-duty vehicles and light-duty trucks included several changes to 40 CFR part 86, subpart S, that should not apply for chassis-certified HD pickups and vans. Based on our experience implementing the Phase 1 program, we believe it is appropriate to include the GHG standards for chassis-certified HD pickups and vans in the same part as light-duty vehicles (40 CFR part 86, subpart S). All other certification requirements for these heavy-duty vehicles—criteria exhaust standards, evaporative and refueling standards, provisions for onboard diagnostics, and the range of certification and compliance provisions—are in that subpart. We note that we have not experienced the same challenges for other heavy-duty vehicles, and are therefore not relocating the other provisions of 40 CFR part 1037.

This migration has highlighted a few areas where we need to clarify how the regulations apply for chassis-certified HD pickups and vans. In particular, EPA is adopting the following changes:

- Clarify that the GHG standards apply at high-altitude conditions.
- State that fleet-average calculation of carbon-related exhaust emissions

(CREE) is not required for chassis-certified HD pickups and vans. Instead, heavy-duty vehicles are subject to CO₂ standards.

- Clarify that requirements related to model types and production-weighted average calculation apply only for passenger automobiles and light trucks.
- State that the credit and debit provisions of 40 CFR 86.1865–12(k)(5) do not apply for chassis-certified HD pickups and vans.
- Clarify that the Temporary Lead Time Allowance Alternative Standards in 40 CFR 86.1865–12(k)(7) do not apply for chassis-certified HD pickups and vans.
- State that the early credit provisions of 40 CFR 86.1866–12, 86.1867–12, 86.1868–12, 86.1869–12, 86.1870–12, and 86.1871–12 do not apply for chassis-certified HD pickups and vans.

(2) Heavy-Duty Engines

EPA is revising the approach to classifying gaseous-fuel engines with respect to both GHG and criteria emission standards. The general approach is to continue to divide these engines into spark-ignition and compression-ignition categories, but we will apply the compression-ignition standards to all engines that qualify as heavy heavy-duty engines based on the primary intended service class.⁹⁷⁷ Previously, any gaseous-fuel engine derived from a gasoline engine was subject to the spark-ignition standards no matter the weight class of the vehicle. As described in Section II, EPA now believes this approach does not reflect the reality that engines used in Class 8 vehicles compete directly with diesel engines. We believe they should therefore be required to meet the same emission standards. Because all current gaseous-fuel engines for these large vehicles are already being certified to the compression-ignition engine standards, we can apply this approach to engines subject to the HD GHG Phase 1 standards without adverse impacts on any manufacturers. We proposed this same approach for medium heavy-duty engines, but have revised the rule in response to comments objecting to the change; the final rule instead applies standards to these engines as spark-ignition or compression-ignition based only on each engine's characteristics. We believe this is appropriate because

⁹⁷⁷ Engine classification is set forth in 40 CFR 1036.801. Spark-ignition means relating to a gasoline-fueled engine or any other type of engine with a spark plug (or other sparking device) and with operating characteristics similar to the Otto combustion cycle. Compression-ignition engines are reciprocating internal-combustion engines that are not spark-ignition engines.

a substantial number of medium heavy-duty vehicles use gasoline-fueled engines, and gaseous-fueled engines used in these vehicles would therefore not always be competing directly with diesel-fueled engines as the main alternative.

EPA is also revising the regulation to spell out how to apply enforcement liability for a situation in which the *engine* manufacturer uses deficit credits for one or more model years. Simply put, any time an engine manufacturer is allowed to carry a deficit to the next year, all enforcement liability for the engines that generated the deficit are extended for another year. These provisions are the same as what we have already adopted for heavy-duty *vehicles* subject to GHG standards under 40 CFR part 1037.

(3) Evaporative Emission Testing for Natural Gas Vehicles

Heavy-duty vehicles fueled by natural gas have for many years been subject to evaporative emission standards and test procedures. While fuel systems containing gasoline require extensive design features to handle vented fuel, fuel systems containing natural gas generally prevent evaporative losses by remaining sealed. In the case of compressed natural gas, there is a voluntary consensus standard, ANSI NGV1–2006, that is designed to ensure that there are no leaks or losses during a refueling event. Since compressed natural gas systems remain sealed indefinitely once the refueling event is complete, we understand that complying with the ANSI refueling standard is sufficient to demonstrate that the vehicle also complies with all applicable evaporative emission standards. The Light-Duty Tier 3 final rule included provisions to clarify that compressed natural gas systems meeting the applicable ANSI standard are deemed to comply with EPA's evaporative emission standards. In response to comments received on the proposed rule, we are adding a reference to a supplemental ANSI standard that similarly specifies system-integrity requirements for CNG-fueled heavy-duty vehicles that allow for substantially higher refueling rates; this supplemental standard will eventually be incorporated into ANSI NGV1.

Systems using liquefied natural gas (LNG) behave similarly, except that the cryogenically stored fuel needs to be vented to prevent an over-pressure situation if the vehicle is not used for an extended time, as described in Section XI. Such vehicles are currently subject to evaporative emission standards and test procedures, though there are some

substantial questions about how one can best apply the procedures to these systems; not all of the instructions about preconditioning the vehicle are straightforward for cryogenic fuel systems with no evaporative canister. EPA is adopting an approach that is similar to what applies for compressed natural gas systems, which needs some additional attention to address boil-off emissions. SAE J2343 is a voluntary consensus standard that specifies a recommended practice to establish a minimum five-day hold time before boil-off starts to occur for LNG systems. EPA is adopting a requirement that manufacturers of LNG vehicles meet the SAE J2343 standard as a means of demonstrating compliance with evaporative and refueling emission standards.

While the hold-time requirements of SAE J2343 are clear, there appears to be very little description of the procedure to determine how much time passes between a refueling event and initial venting. To ensure that all manufacturers are subject to the same set of requirements, we are adding a minimal set of specifications corresponding to the demonstration under SAE J2343. In particular, the regulation specifies that the tank must remain at rest throughout the measurement procedure, ambient temperatures must remain between 20 and 30 °C, and the hold-time period starts when the tank pressure reaches 690 kPa (100 psi) after a conventional refueling event. We are also adopting a simplified standard that translates the five-day hold time into a maximum allowable pressure build over a shorter time for parked vehicles. In particular, for vehicles parked for at least 12 hours, tank pressure must not increase by more than an average of 9 kPa (1.3 psi) per hour. The pressure increase corresponding to the five-day hold-time standard is about 7.5 kPa per hour. The additional margin is intended to account for variability related to different ambient conditions, vehicle handling, nonlinear pressure increases, measurement instruments, and other factors. This is intended to give vehicle owners a more practical performance measure to evaluate whether tanks continue to meet the hold-time requirement.

Manufacturers may rely on SAE J2343 to meet evaporative and refueling standards immediately with completion of the final rule; this demonstration becomes mandatory for vehicles produced on or after January 1, 2020.

One commenter suggested that we add a reference to European test protocols for CNG heavy-duty vehicles

to allow for a higher refueling flow rate than is allowed under the EPA regulations, which are based on hardware and procedures for light-duty vehicles (ANSI NGV1). We learned that the European protocol is based on systems up to 3000 psi and is therefore not valid for most heavy-duty CNG vehicles in the United States. Representatives of the natural gas industry responded to the comment suggesting the European protocol by recommending that we instead reference a recently published supplement to ANSI NGV1, which accommodates the higher flow rates corresponding to heavy-duty vehicles and current refueling technology. We are accordingly revising the regulation to reference this additional ANSI document, which is known as CSA IR-1–15, “Compressed Natural Gas Vehicle (NGV) High Flow Fueling Connection Devices.”

(4) Compliance and Other General Provisions

EPA is adopting the following changes that apply broadly for different types of vehicles or engines:

- Providing additional detail about manufacturers obligations with respect to delegated assembly. In response to comments, we have delayed the applicability of these provisions until January 1, 2018 to provide manufacturers with additional lead time. See 40 CFR 1037.150(e) and 1037.621.
- Add a requirement for vehicle manufacturers that sell incomplete vehicles to secondary vehicle manufacturers to provide emission-related assembly instructions to ensure that the completed vehicle will be in a certified configuration.
- Specify parameters for determining a vehicle’s curb weight, consistent with current practice for vehicles certified under 40 CFR part 86, subpart S.
- Revise the recordkeeping requirement to specify a uniform eight-year retention period for all data supporting an application for certification. The provision allowing for one-year retention for “routine data” is no longer necessary now that data collection is all recorded in electronic format. EPA is also clarifying that the eight-year retention period is calculated relative to the latest associated application for certification, not from the date the data were generated.
- Change the rounding for analytically derived CO₂ emission rates and target values from the nearest 0.1 g/mile to the nearest 1 g/mile.

- Clarify how manufacturers may amend an application for certification after the end of the model year.

- Remove the general recordkeeping provisions from 40 CFR 1037.735 that are already described in 40 CFR 1037.825.

- Clarify how EPA will conduct selective enforcement audits (SEAs) for engines (in 40 CFR 1036.301) and vehicles and components (in 40 CFR 1037.301–1037.320) with respect to GHG emissions.

- Add provisions to provide a streamlined path for off-cycle credit for adding Phase 2 technologies to Phase 1 vehicles. See 40 CFR 1037.150.

EPA proposed a different equation with a ratio of 0.8330 in 40 CFR 1037.525 for the case of full yaw sweep measurements to determine wind-averaged drag correction as an amendment to the Phase 1 program. Some commenters argued that this change would impact stringency, but we disagree because manufacturers are already subject to EPA compliance using both methods (full yaw sweep and ± 6 degree measurements), and this Phase 1 flexibility was not used in setting the level of the Phase 1 standards. Nevertheless, we are adopting the final rule without this change to the Phase 1 standards. Other changes in the existing Phase 1 regulations for MY 2017 will serve to mitigate any impacts, and the agencies are no longer convinced the potential disruption to manufacturers’ compliance plan is warranted.

B. Other Compliance Provisions for NHTSA

(1) Standards and Credit Alignment

In Phase 1, the agencies intended GHG and fuel consumption standards for segments of the National Program to be in alignment so that manufacturers will not be required to build vehicles to meet in equivalent standards. Despite the intent, NHTSA and EPA have identified several scenarios where credits and compliance to both sets of standards are not aligned. This misalignment can have various impacts on compliance with the National Program.

For example, a manufacturer of tractors could have two vehicle families that with same number of vehicles but with opposite and equal compliance margins with standards. In this scenario, the first family will over-comply with the GHG standard while the second family will under-comply with the GHG standard by the same amount of grams CO₂/ton-mile. In calculating credits, the manufacturer will have a net of zero

GHG credits and exactly meet compliance; however, based on conversions and rounding of the standard and performance results that manufacturer could end up earning credits or having a credit deficit under NHTSA's fuel efficiency program.

In order to correct this misalignment, NHTSA proposed to amend the existing fuel consumption standards and the method for calculating performance values for all compliance categories by increasing the significant digits in these conversion values. Increasing the significant digits in these values will result in more precise alignment between final compliance credit balances.

NHTSA proposed that the increase resolution would apply retroactively starting for the model year 2013 standard. However, because the Phase 1 fuel consumption standards created a difference in compliance margins which could potentially have an adversely impact for certain manufacturers who have already developed engineering plans considering previous credit balance, NHTSA sought comments on whether optional to allow manufacturer to continue using the Phase 1 standards. No comments were received in response.

NHTSA is finalizing its standards and performances for the Phase 1 and 2 programs with increased significant digits as the only option for compliance. Retaining the previous accuracy does not maintain a single national program and aligning credit balances is more important because it ensures the same compliance outcome. Manufacturers who may have planned their compliance strategies using the previous approach would not be able to take advantage of any relaxations in the NHTSA program because the national program requires one single compliance fleet and manufacturers would still need to comply with the more stringent EPA standards.

(2) Off-Road Exemption Petition Process for Tractors and Vocational Vehicles

In the Phase 1 final rule, the agencies added provisions for certain types of vocational tractors and vocational vehicles that operate off-road to be exempt from standards, although standards will still apply to the engines installed in these vehicles. An exemption was warranted because these vehicles operate in a manner essentially making them incompatible with fuel saving and emission reduction technologies, such as performing work in an off-road environment, being speed restricted, or having off-road components or other features making

them incompatible for roadways. For the Phase 1 program, off-road vehicle manufacturers meeting the exemption provisions are required to provide EPA and NHTSA, through the EPA database, a report within 90 days after the end of each model year identifying its off-road vehicles. The report must provide a description of each excluded vehicle configuration, including an explanation of why it qualifies for the exclusion and the production volume. A manufacturer having an off-road vehicle that does not meet the criteria under the agencies' off-road exemptions in 40 CFR 1037.631 and 49 CFR 535.5 is allowed to submit a petition under 40 CFR 1037.150(h) and 49 CFR 535.8 describing how and why its vehicles should qualify for exclusion based on criteria that are equivalent to those specified in 40 CFR 1037.631.

Under Phase 1 compliance processes, manufacturers have not been using the petitioning process to get approval of an exemption for off-road vehicles that do not meet the specified criteria to qualify for an exemption. Instead, manufacturers have been submitting information to EPA during production for a given model year to determine whether or not these vehicles qualify for an exemption, or if they need to get certificates of conformity for the vehicles they already produced. EPA and NHTSA collaboratively determine whether manufacturers should qualify for an exemption under 40 CFR 1037.150(h) and 49 CFR 535.8, and EPA shares the decision with the manufacturer.

For the Phase 1 and 2 standards, the agencies are revising the regulations to clarify the process for vehicle manufacturers to get approval for an exemption in unusual circumstances in which the vehicle should be exempt even though it does not automatically qualify for an exemption under the criteria specified in 40 CFR 1037.631 and 49 CFR 535.5. Most importantly, we now specify at 40 CFR 1037.150(h) and 49 CFR 535.8 that manufacturers must get approval for the exemption before producing the subject vehicles to avoid violating statutory prohibitions. EPA and NHTSA will continue to collaborate in making any final decisions on exemptions.

Note that vehicles meeting the qualifying criteria under 40 CFR 1037.631 and 49 CFR 535.5 are exempt without request; however, if manufacturers want to address any uncertainty by getting EPA and NHTSA to affirm that their vehicles do in fact meet the specified criteria, they may ask for preliminary approval under 40 CFR 1037.210.

(3) Innovative Technology Request Documentation Specifications

For vehicle and engine technologies that can reduce GHG and fuel consumption, but for which there is not yet an established method for quantifying reductions, the agencies encourage the development of such technologies through providing "innovative technology" credits. Manufacturers seeking innovative technology credits must quantify the reductions in fuel consumption and GHG emissions that the technology is expected to achieve, above and beyond those achieved on the existing test procedures.

Manufacturers submitting innovative technology requests must send a detailed description of the technology and a recommended test plan to EPA as detailed in 40 CFR 1036.610 and 1037.610. The test plan must include whether the manufacturer is applying for credits using the improvement factor method or the separate-credit method. It is recommended that manufacturers not conduct testing until the agencies can collaboratively approve the test plan in which a determination is made on the qualification of the technology as innovative. EPA in consultation with NHTSA also makes the decision at that time whether to seek public comments on the test plan if there are unknown factors in the test methodology.

The agencies have received feedback from manufacturers that the final approval process is not clearly defined, which has caused a substantial time commitment from manufacturers. To address this feedback, for the final rule, the agencies are adopting further clarification in 40 CFR 1036.610 and 1037.610 defining the steps manufacturers must follow after an approval is granted for a test plan. This includes specifications for submitting the final documentation to the agencies for final approval and for determining credit amounts. The agencies are adding the same level of detail as required for the final documentation required in EPA's light duty off-cycle program in 40 CFR 86.1869–12(e)(2). These specifications should provide manufacturers with a clear understanding of the required documentation and approval process to reduce the time burden placed on manufacturers.

NHTSA is also adding similar provisions from its light duty CAFE program specified in 49 CFR 531.6(b)(2) and 533.6(c)(2) for limiting the approval of innovative technologies under its program for those technologies related to crash-avoidance technologies, safety

critical systems or systems affecting safety-critical functions, or technologies designed for the purpose of reducing the frequency of vehicle crashes. NHTSA prohibited credits for these technologies under any circumstances in its CAFE program (see 77 FR 62730). NHTSA believes a similar strategy is warranted for heavy-duty vehicle as well.

(4) Credit Acquisition Plan Requirements

The National Program was designed to provide manufacturers with averaging, banking and trading (ABT) flexibilities for meeting the GHG and fuel efficiency standards to optimize the effectiveness of the program. As a part of these flexibilities, manufacturers generating a shortfall in fuel consumption credits for a given model year must submit a credit plan to NHTSA describing how it plans to resolve its deficits within 3 models year. To assist manufacturers, NHTSA is modify 49 CFR 535.9(a)(6) of its regulation to clarify and provide guidance to manufacturers on the requirements for a credit allocation plan which contains provisions to acquire credits from another manufacturer which will be earned in future model years.

The current regulations do not specify if future credit acquisition is permitted or not and the revision is intended to clarify that it is, with respect to the limitation a credit shortfall can only be carried forward three years. Providing this clarification is intended to increase transparency within the program and ensure all manufacturers are aware of its available flexibilities. NHTSA is adopting the requirement that in order for a credit allocation plan to be approved, NHTSA will require an agreement signed by both manufacturers. This requirement will assist NHTSA with its determination that the credits will become available to the acquiring manufacturer when they are earned.

(5) New Vehicle Field Inspections and Recordkeeping Requirements

Previously, NHTSA decided not to include recordkeeping provisions in its regulations for the Phase 1 program. EPA regulations include recordkeeping requirements in 40 CFR 1036.250, 1036.735, 1036.825, 1037.250, 1037.735, and 1037.825. For the Phase 2 program, NHTSA is adding recordkeeping provisions to facilitate its compliance validation program for the final rule. For the Phase 1 and 2 programs, manufacturers test and conduct modeling to determine GHG emissions and fuel consumption performance, and

EPA and NHTSA perform validation testing. EPA uses the results of the validation tests to create a finalized report that confirms the manufacturer's final model year GHG emissions and fuel consumption results. Each agency will use this report to enforce compliance with its standards.

NHTSA assesses compliance with fuel consumption standards each year, based upon EPA final verified data submitted to NHTSA for its heavy-duty vehicle fuel efficiency program established pursuant to 49 U.S.C. 32902(k). NHTSA may conduct verification testing throughout a given model year in order to validate data received from manufacturers and will discuss any potential issues with EPA and the manufacturer. See 49 CFR 535.9. After the end of the model year, NHTSA may also decide to conduct field inspections in order to confirm whether or not a new vehicle was manufactured as originally certified. NHTSA may conduct field inspections separately or in coordination with EPA. To facilitate inspections, the agencies will add additional provisions to the EPA recordkeeping provisions to require manufacturers to keep build documents for each manufactured tractor or vocational vehicle. Each build document will be required to contain specific information on the design, manufacturing, equipment and certified components for a vehicle. NHTSA will request build documents through EPA and the agencies will collaborate on the finding of all field inspections. Manufacturers will be required to keep records of build documents for a period of 8 calendar years.

XIII. Other Regulatory Provisions

In addition to the new GHG standards in these rules, EPA and NHTSA are amending various aspects of the regulations as part of the HD GHG Phase 1 standards for heavy-duty highway engines and vehicles, as described in Section XII. EPA is also taking the opportunity to amend regulatory provisions for other requirements that apply for heavy-duty highway engines, and for certain types of nonroad engines and equipment.

Most of the amendments described in this section represent minor technical issues and, as such, were not the subject of extensive comment. Two exceptions are the issues related to glider kits and to competition vehicles, as noted below. The rest of this section, for which we received fewer comments, generally includes only references to the more significant comments, such as comments that impacted our conclusions for the provisions adopted

in the final rule. See the RTC for a more complete discussion of the comments.

For the convenience of the reader, we are republishing some related text that is not being amended. We note, however, that we have not reopened the standards or other fundamental aspects of these programs that remain unchanged substantively.

A. Amendments Related to Heavy-Duty Highway Engines and Vehicles

This section describes a range of regulatory amendments for heavy-duty highway engines and vehicles that are not directly related to GHG emission standards. Note that Section XIII. B. describes new requirements for glider kits and Section XIII. F. describes additional changes related to test procedures that affect heavy-duty highway engines.

(1) Alternate Emission Standards for Specialty Heavy-Duty Vehicles

Motor vehicles conventionally comprise a familiar set of vehicles within a relatively narrow set of parameters—motorcycles, cars, light trucks, heavy trucks, buses, etc. The definition of “motor vehicle;” however, is written broadly to include a very wide range of vehicles. Almost any vehicle that can be safely operated on streets and highways is considered a motor vehicle under 40 CFR 85.1703. Development of EPA's emission control programs is generally focused on a consideration of the technology, characteristics, and operating parameters of conventional vehicles, and typically includes efforts to address concerns for special cases. For example, the driving schedule for light-duty vehicles includes a variation for vehicles that are not capable of reaching the maximum speeds specified in the Federal Test Procedure.

Industry innovation in some cases leads to some configurations that make it particularly challenging to meet regulatory requirements. We are aware that plug-in hybrid-electric heavy-duty vehicles are an example of this. An engine for such a vehicle is expected to have a much lower power rating and duty cycle of engine speeds and loads than a conventional heavy-duty engine. The costs of regulatory compliance and the mismatch to the specified duty cycle can make it cost-prohibitive for engine manufacturers to certify such an engine under the heavy-duty highway engine program.

To address concerns about certifying atypical engines to highway heavy-duty standards for use in hybrid vehicles, we are therefore adopting a provision allowing manufacturers of heavy-duty

highway vehicles the option to install limited numbers of engines certified to alternate standards. Qualifying engines would be considered motor vehicle engines, but they may be certified to standards that are based on standards adopted for comparable nonroad engines. EPA's nonroad emission standards have reached a point that involves near parity with the level of emission control represented by the emission standards for heavy-duty highway engines. EPA developed these provisions especially for vehicles with hybrid powertrains; however, the same principles apply for three other unusual vehicles types: amphibious vehicles, vehicles with maximum speed at or below 45 miles per hour, and as described below, certain all-terrain vehicles. We are therefore applying the same provisions to these additional vehicles.

California ARB suggested that we limit relief to hybrid vehicles that have a series configuration, or to hybrid vehicles that have a minimum all-electric range. We chose not to adopt these limitations because these features are not fundamental to what we believe is the basis for accommodating special vehicle designs. For example, if a vehicle needs a 20-kW gasoline engine to recharge batteries used for propulsion, and provides a small amount of power directly to the wheels, we believe this should not be disqualified from using the specialty-vehicle provisions because there is no expectation that 20 kW engines will be certified to the conventional highway heavy-duty engine standards anytime in the foreseeable future.

We proposed to offer this flexibility for hybrids, amphibious vehicles, and low-speed vehicles. We also received comment advocating that certain qualifying all-terrain vehicles are in a similar situation since they have unique engine-performance requirements that prevent them from finding compliant highway engines; we have modified the rule to also apply the specialty vehicle provisions to these all-terrain vehicles. The regulations will limit this allowance to vehicles that have portal axles, which are specialized axles that increase ground clearance. Cost and/or performance limits for such axles preclude their use for vehicles intended for use primarily on highways. Thus, we believe vehicles with such axles are designed primarily for off-road operation, while retaining the ability to occasionally operate on highways.

Under approach being adopted for these various vehicles, compression-ignition engines could be certified to alternate standards that are equivalent

to the emission standards under 40 CFR part 1039, and spark-ignition engines could be certified to alternate standards that are equivalent to the Blue Sky emission standards under 40 CFR part 1048.⁹⁷⁸ In response to a comment from California ARB, we are adopting a requirement that compression-ignition engines also meet a PM standard (Family Emission Limit) of 0.020 g/kW-hr corresponding to the PM standard that applies for heavy-duty highway engines. Similarly, we are adopting an N₂O standard of 0.1 g/kW-hr for SCR-equipped diesel-fueled engines that corresponds to the N₂O standard that applies for heavy-duty highway engines. This collection of standards aligns with our expectation that such engines would generally be expected to use the same technologies to control emissions as engines certified to the applicable emission standards for heavy-duty highway engines. (The regulation being finalized disallows this approach for compression-ignition engines below 56 kW since the nonroad standards for those engines are substantially less stringent than the standards that apply for heavy-duty highway engines). Also, since the nonroad duty cycles generally better represent the in-use operating characteristics of engines in these specialty vehicles, we expect the nonroad test procedures to be at least as effective in achieving effective in-use emission control. The regulations at 40 CFR part 1048 include a simplified form of diagnostic controls, and we are adopting in these rules a simplified diagnostic control requirement for 40 CFR part 1039. These engine-based diagnostic controls substitute for the diagnostic requirements specified in 40 CFR 86.010–18. Note that the diagnostic requirements apply for *engine* systems or components; as such, we generally apply those diagnostic requirements to hybrid powertrain systems and components only if the engine manufacturer includes those features or parameters as part of the certified configuration for their engines. We may revisit issues related to diagnostic requirements for hybrid systems in a future rulemaking.

These alternate standards relate primarily to the engine certification-based emission standards and certification requirements. All vehicle-based requirements for evaporative emissions continue to apply as specified in the regulation. In addition, hybrid vehicles would still be subject to all the standards and requirements that apply to heavy-duty vehicles under 40 CFR

part 1037. For example, manufacturers would need to perform powertrain testing and run GEM to determine the applicable g/ton-mile emission rate for hybrid vehicles. However, the agencies are not requiring vehicle certification for the three other types of specialty vehicles. Low-speed vehicles are already excluded from the vehicle requirements under Phase 1, while the amphibious and all-terrain vehicles would present significant challenges to the vehicle simulations.

This allowance is intended to lower the barrier to introducing innovative technology for motor vehicles. It is not intended to provide a full alternative compliance path to avoid certifying to the emission standards and control requirements for highway engines and vehicles. To accomplish this, EPA will allow a manufacturer to produce no more than 1,000 hybrid vehicles in a single model year under this program, and no more than 200 amphibious vehicles, all-terrain vehicles, or speed-limited vehicles. In the case of hybrid vehicles, we are also acting on California ARB's request that we adopt a sunset provision for hybrid vehicles; accordingly, the simplified certification applies only through model year 2027. In the meantime we will monitor implementation of the program and consider whether there is any long-term need for these or other streamlined certification provisions for hybrid vehicles.

As described in the proposed rule, California ARB is in the process of developing similar provisions for a reduced compliance burden for qualifying highway vehicles toward the goal of incentivizing vehicles with hybrid powertrains and low-NO_x engines. The incentives generally consist of allowing specific OBD variances or deficiencies (for low-NO_x engines) or broadly waiving OBD requirements (for hybrid vehicles). To the extent that California ARB certifies vehicles based on approving OBD deficiencies, we would apply a similar discretion for 49-state certification of the same engine model to allow for nationwide sale of those products. If California ARB approves certification of hybrid systems in which the highway OBD requirements are mostly or entirely waived, we would expect to apply the provisions described in this section to allow vehicle manufacturers to produce up to 1000 such vehicles in a given year.

(2) Chassis Certification of Class 4 Heavy-Duty Vehicles

In the HD Phase 1 rule, the agencies included a provision allowing manufacturers to certify Class 4 and

⁹⁷⁸ Blue Sky standards are voluntary low-emission standards under 40 CFR part 1048.

larger heavy-duty vehicles to the chassis-based emission standards in 40 CFR part 86, subpart S. This applied for greenhouse gas emission standards, but not criteria emission standards. EPA revisited this issue in the recent Tier 3 final rule, where we revised the regulation to allow this same flexibility relative to exhaust emission standards for criteria pollutants. However, this change to the regulation conflicted with our response to a comment in that rulemaking that EPA should not change the certification arrangement for criteria pollutants.

EPA requested comment on how best to address this issue in a way that resolves the various and competing concerns. Commenters argued for and against allowing certification of the heavier vehicles to chassis-based emission standards. In the final rule, we are adopting a limited allowance to certify vehicles above 14,000 pounds GVWR using chassis-based certification procedures of 40 CFR part 86, subpart S. In particular, manufacturers may rely on chassis-based certification for heavier vehicles only if there is a family with vehicles at or below 14,000 pounds GVWR that can properly accommodate the bigger vehicles as part of the same family. As part of this arrangement, chassis-certified vehicles above 14,000 pounds GVWR may not rely on a work factor that is greater than the largest work factor that applies for vehicles at or below 14,000 pounds GVWR from the same family.

(3) Nonconformance Penalties (NCPs)

The Clean Air Act requires that heavy-duty standards for criteria pollutants such as NO_x reflect the greatest degree of emission reduction achievable through the application of technology that EPA determines will be available. Such “technology-forcing” standards create the risk that one or more manufacturers may lag behind in the development of their technology to meet the standard and, thus, be forced out of the marketplace. Recognizing this risk, Congress enacted CAA section 206(g) (42 U.S.C. 7525(g)), which requires EPA to establish “nonconformance penalties” to protect these technological laggards by allowing them to pay a penalty for engines that temporarily are unable to meet the applicable emission standard, while removing any competitive advantage those technological laggards may have.

On September 5, 2012, EPA adopted final NCPs for heavy heavy-duty diesel engines, which were available to manufacturers of heavy-duty diesel engines unable to meet the current oxides of nitrogen (NO_x) emission

standard. On December 11, 2013, the U.S. Court of Appeals for the District of Columbia Circuit issued an opinion vacating that Final Rule. It issued its mandate for this decision on April 16, 2014, ending the availability of the NCPs for the current NO_x standard, as well as vacating certain amendments to the NCP regulations, due to concerns about inadequate notice. In particular, the amendments revised the text explaining how EPA determines when NCPs should be made available. In the NPRM for this rulemaking, EPA proposed to remove the vacated regulatory text specifying penalties, and re-proposed most of the other vacated amendments. Having now provided this additional notice and a full opportunity for comment, we believe that it is appropriate to finalize the proposed changes. EPA is also adopting the proposed new 40 CFR 86.1103–2016 to replace the existing 40 CFR 86.1103–87.

(a) Vacated Penalties

In EPA’s regulations, NCP penalties are calculated from inputs specific to the standards for which NCPs are available. The input values are specified in 40 CFR 86.1105–87. EPA is removing paragraph (j) of this section which specifies the vacated inputs for the 2010 NO_x emission standard. Since all manufacturers are currently complying with these standards, and the court vacated the text in question, it no longer has any purpose.

(b) Re-Proposed Text

The 2012 rule made amendments to four different sections in 40 CFR part 86. The amendments to 40 CFR 86.1104–91 and 86.1113–87 were supported during the rulemaking and were not questioned in the Court’s decision. Nevertheless, these revisions were vacated along with the rest of the rule. In the NPRM, EPA re-proposed these changes, even though we had already provided full notice and opportunity for public comment for these changes. Since we are adopting text that is already in the CFR, the final rule consists of leaving these sections of the regulations unchanged.

(i) Upper Limits

The changes to 40 CFR 86.1104–91 affect the upper limit. The upper limit (UL) is the emission level established by regulation above which NCPs are not available. A heavy duty engine cannot use NCPs to be certified for a level above the upper limit. CAA section 206(g)(2) refers to the upper limit as a percentage above the emission standard, set by regulation, that corresponds to an emission level EPA determines to be

“practicable.” The upper limit is an important aspect of the NCP regulations not only because it establishes an emission level above which no engine may be certified using NCPs, but it is also a critical component of the cost analysis used to develop the penalty rates. The regulations specify that the relevant costs for determining the COC50 and the COC90 factors are the difference between an engine at the upper limit and one that meets the applicable standards (see 40 CFR 86.1113–87).

The regulatory approach adopted under the prior NCP rules set the upper limit at the prior emission standard when a prior emission standard exists and is then changed to become more stringent. EPA concluded that this upper limit should be reasonably achievable by all manufacturers with engines or vehicles in the relevant class. It should be within reach of all manufacturers of HD engines or HD vehicles that are currently allowed so that they can continue to sell their engines and vehicles while finishing their development of fully complying engines. A manufacturer of a previously certified engine or vehicle should not be forced to immediately remove a HD engine or vehicle from the market when an emission standard becomes more stringent. The prior emission standard generally meets these goals because manufacturers have already certified their vehicles to that standard.

One of EPA’s changes to the regulations in 40 CFR 86.1104–91 clarifies that EPA may set the upper limit at a level below the previous standard if we determine that the lower level is achievable by all engines or vehicles in the relevant subclass. This was the case for the vacated NCP rule. Another change allows us to set the upper limit at a level above the previous standard in unusual circumstances, such as where a new standard for a different pollutant, or other requirement, effectively increases the stringency of the standard for which NCPs would apply. This occurred for heavy heavy-duty engines with the 2004 standards.

(ii) Payment of Penalties

The changes to 40 CFR 86.1113–87 correct EPA organizational units and mail codes to which manufacturers must send information. The previous information is no longer valid.

(c) Criteria for the Availability of NCPs

Since the promulgation of the first NCP rule in 1985, subsequent NCP rules generally have been described as continuing “phases” of the initial NCP

rule. The first NCP rule (Phase 1), sometimes referred to as the “generic” NCP rule, established three basic criteria for determining the eligibility of emission standards for nonconformance penalties in any given model year (50 FR 35374, August 30, 1985). (For regulatory language, see 40 CFR 86.1103–87). The first criterion is that the emission standard in question must become more difficult to meet. This can occur in two ways, either by the emission standard itself becoming more stringent, or due to its interaction with another emission standard that has become more stringent. Second, substantial work must be required in order to meet the emission standard. EPA considers “substantial work” to mean the application of technology not previously used in that vehicle or engine class/subclass, or a significant modification of existing technology, in order to bring that vehicle/engine into compliance. EPA does not consider minor modifications or calibration changes to be classified as substantial work. Third, EPA must find that a manufacturer is likely to be noncomplying for technological reasons (referred to in earlier rules as a “technological laggard”). Prior NCP rules have considered such a technological laggard to be a manufacturer who cannot meet a particular emission standard due to technological (not economic) difficulties and who, in the absence of NCPs, might be forced from the marketplace. During the 2012 rulemaking, some commenters raised issues relating to EPA’s interpretation of these criteria:

- The extent to which the criteria are intended to constrain EPA’s ability to set NCPs
- The timing for evaluating the criteria
- The meaning of technological laggard

As its primary finding in the 2013 decision, the Court stated that EPA had not provided sufficient notice or opportunity for comment regarding its interpretation of these criteria. To address the Court’s notice and comment concern, EPA solicited comments in the Phase 2 NPRM on our proposed revisions to these criteria. Note that we proposed changes that are different from those at issue during the court case.

(i) Constraints on EPA

Several commenters on the 2012 rule argued (implicitly or explicitly) that EPA cannot establish NCPs unless all of the regulatory criteria for NCPs (in 40 CFR 86.1103–87) are met. Some went further to argue that EPA must demonstrate that the criteria are met.

However, the actual regulatory text has never stated that EPA may establish NCPs only if all criteria are met, but rather that EPA shall establish NCPs “provided that EPA finds” the criteria are met. These criteria were included in the regulations to clarify that manufacturers should not expect EPA to initiate a rulemaking to establish NCPs where these criteria were not met. Moreover, the regulations clearly defer to EPA’s judgment for finding that the criteria are met. While EPA must explain the basis of our finding, the regulatory language does not require us to prove or demonstrate that the criteria are met.

This interpretation is consistent with the text of the Clean Air Act, which places no explicit restrictions on when EPA can set NCPs. In fact, it seems to create a presumption that NCPs will be available. The Act actually requires EPA to allow certification of engines that do not meet the standard unless EPA determines the practicable upper limit to be equal to the new emission standard.

To address this confusion, the revised regulatory text explicitly states that where EPA cannot determine if all of the criteria have been met, we may presume that they have. In other words, EPA does not have the burden to prove they have been met. This policy was opposed by Volvo in its comments to this current rulemaking. It stated that EPA findings “must be subject to public review and scrutiny” to “adequately protect complying manufacturers’ competitive interests.” However, EPA sees no basis in the Act to believe that Congress intended EPA to protect complying manufacturers by denying a request for NCPs. Rather, Congress directed EPA to *set the penalty* at a level that would “remove any competitive disadvantage to manufacturers whose engines or vehicles achieve the required degree of emission reduction.”⁹⁷⁹

Under the changes being adopted here, compliant manufacturers would retain the ability to challenge whether or not EPA had set penalties at a level that protects them.

(ii) Timing for Evaluating Criteria

In order to properly understand the appropriate timing for evaluating each of the NCP criteria, it is necessary to understand the purpose of each. When considered together, these criteria evaluate the likelihood that a manufacturer will be technologically unable to meet a standard on time. However, when EPA initially proposed the NCP criteria, we noted that the first

two criteria addressed whether there was a possibility for a technological laggard to develop. When the first criterion (that there be a new standard) is met, it creates the possibility for a technological laggard to exist. When manufacturers must perform substantial work (as required for the second criterion), it is possible that at least one will be unsuccessful and will become a laggard. Thus, when evaluating these first two criteria, the purpose is to determine whether the standard created the possibility for a laggard to exist. The third criterion is different because it asks whether that *possibility* has turned into a *likelihood* that a technological laggard has developed. For example, a standard may become significantly more stringent and substantial effort might be required for compliance, but all manufacturers may be meeting the applicable standard. In that situation, a technological laggard is not likely and penalties would be unnecessary.

In this context, it becomes clear that since the first two of these criteria are intended to address the question of whether a given standard creates the possibility for this to occur, they are evaluated before the third criterion that addresses the likelihood that the possibility will actually happen. In most cases, it is possible to evaluate these criteria at the point a new standard is adopted. This is the value of these criteria, that they can usually be evaluated long before there is enough information to know whether a technological laggard is actually likely. For example, where EPA adopts a new standard that is not technology-forcing, but rather merely an anti-backsliding standard, EPA could determine at the time it is adopted that the second criterion is not met so that manufacturers would know in advance that no NCPs will be made available for that standard.

One question that arose in the 2012 rule involved how to evaluate the second criterion if significant time has passed and some work toward meeting the standard has already been completed. To address this question, the revised text clarifies that this criterion is to be evaluated based on actual work needed to go from meeting the previous standard to meeting the current standard, regardless of the timing of such changes. EPA looks at whether “substantial work” is or was required to meet the revised standard at any time after the standard was issued—the important question is whether manufacturers who were using technology that met the previous standard would need to build upon that technology to meet the revised standard.

⁹⁷⁹ 42 U.S.C. 7525(g)(3)(E).

Other interpretations would seem to be directly contrary to the purpose of the statute, which is designed to allow technological laggards to be able to certify engines even if other manufacturers have met the standard.

(iii) Technological Laggards

Questions also arose in 2012 about the meaning of the term “technological laggard.” While the regulations do not define “technological laggard,” EPA has previously interpreted this as meaning a manufacturer who cannot meet the emission standard due to technological difficulties, not merely economic difficulties (67 FR 51464–51465, August 8, 2002). Some have interpreted this to mean that NCPs cannot be made available where a manufacturer tries and fails to meet a standard with one technology but knew that another technology would have allowed them to meet the standard. In other words, that it made a bad business decision. However, EPA’s reference to “economic difficulties” applies where a technological path exists—at the time EPA is evaluating the third criterion—that would allow the manufacturer to meet the standard on time, but the manufacturer chooses not to use it for economic reasons. The key question is whether or not the technological path exists at the time of the evaluation. To address this confusion, the revised text clarifies that where there is uncertainty about whether a failure to meet the standards is a technological failure, EPA may presume that it was. Note that this does not mean that EPA might declare any failure to meet standards as a technological failure. The change would only apply where it is not clear.

(4) In-Use Testing

EPA and manufacturers have gained substantial experience with in-use testing over the last four or five years. This has led to important insights in ways that the test protocol can be adjusted to be more effective. EPA is accordingly making the following changes to the regulations in 40 CFR part 86, subparts N and T:

- Revise the NTE exclusion based on aftertreatment temperature to associate the exclusion with the specific aftertreatment device that does not meet the temperature criterion. For example, there should be no NO_x exclusion if a diesel oxidation catalyst is below the temperature threshold. EPA is also revising the exclusion to consider accommodation of CO emissions when there is a problem with low temperatures in the exhaust.
- Clarify that exhaust temperatures should be measured continuously to

evaluate whether those temperatures stay above the 250 °C threshold.

- Add specifications to describe where to measure temperatures for exhaust systems with multiple aftertreatment devices.
- Include a provision to add 0.00042 g/hp-hr to the PM measurement to account for PM emissions vented to the atmosphere through the crankcase vent.
- Increase the time allowed for submitting quarterly reports from 30 to 45 days after the end of the quarter.

(5) Miscellaneous Amendments to 40 CFR Part 86

As described elsewhere, EPA is making several changes to 40 CFR part 86. This includes primarily the GHG standards for Class 2b and 3 heavy-duty vehicles in subpart S. EPA is also making regulatory changes related to hearing procedures, adjustment factors for infrequent regeneration of aftertreatment devices, and the testing program for heavy-duty in-use vehicles.

EPA is making several minor amendments to 40 CFR part 86, including the following:

- Revise 40 CFR 86.1811–17 to clarify that the Tier 2 SFTP for 4,000 mile testing applies to MDPVs, alternative fueled vehicles, and flexible fueled vehicles when operated on a fuel other than gasoline or diesel fuel, even though these vehicles were not subject to SFTP standards under the Tier 2 program. We described this in the Preamble to the Tier 3 final rule, and we are now making this explicit in the regulations.
- Revise 40 CFR 86.1813–17 to clarify that gaseous-fueled vehicles are not subject to the bleed emission test or standard.
- Revise 40 CFR 86.1823 to extend the default catalyst thermal reactivity coefficient for Tier 2 vehicles to also apply for Tier 3 vehicles. This change was inadvertently omitted from the recent Tier 3 rulemaking. EPA will also be interested in a broader review of the appropriate default value for the catalyst thermal reactivity coefficient in some future rulemaking. EPA will be interested in reviewing any available data related to this issue.
- Establish a minimum maintenance interval of 1500 hours for DEF filters for heavy-duty engines. This reflects the technical capabilities for filter durability and the expected maintenance in the field.
- Add crankcase vent filters to the list of maintenance items for heavy-duty engines. This allows manufacturers to specify a maintenance interval of 50,000 miles, or request a shorter interval under § 86.004–25. We are also revising consolidating regulatory provisions in

§ 86.004–25 to allow us to remove § 86.007–25; this reorganization does not change any regulatory requirements.

- Remove the idle CO standard from 40 CFR 86.007–11 and 40 CFR 86.008–10. This standard no longer applies, since all engines are now subject to diagnostic requirements instead of the idle CO standard.
- Revise 40 CFR 86.094–14 to consolidate the streamlined certification procedures for small-volume manufacturers. The consolidated section reduces potential confusion by listing only the provisions that do not apply, rather than trying to create (and maintain) a comprehensive list of all the provisions that apply, in addition to the provisions that do not apply. Except for removing obsolete content, the revised regulation does not include substantive changes to the specified procedures.
- Revise 40 CFR 86.1301 to remove obsolete content.

EPA is also adopting several amendments to remove obsolete text, update cross references, and streamline redundant regulatory text. For example, paragraph (f)(3) of Appendix I includes a duty cycle for heavy-duty spark-ignition engines that is no longer specified as part of the certification process.

(6) Applying 40 CFR Part 1068 to Heavy-Duty Highway Engines and Vehicles

As part of the Phase 1 standards, EPA applied the exemption and importation provisions from 40 CFR part 1068, subparts C and D, to heavy-duty highway engines and vehicles. EPA also specified that the defect reporting provisions of 40 CFR 1068.501 were optional. In an earlier rulemaking, EPA applied the selective enforcement auditing under 40 CFR part 1068, subpart E (75 FR 22896, April 30, 2010). EPA is in this rule adopting the rest of 40 CFR part 1068 for heavy-duty highway engines and vehicles, with certain exceptions and special provisions.

40 CFR part 1068 captures a range of compliance provisions that are common across our engine and vehicle programs. These regulatory provisions generally provide the legal framework for implementing a certification-based program. 40 CFR part 1068 works in tandem with the standard-setting part for each type of engine/equipment. This allows EPA to adopt program-specific provisions for emission standards and certification requirements for each type of engine/equipment while taking a uniform approach to the compliance provisions that apply generally.

Many of the provisions in 40 CFR part 1068 were originally written to align with the procedures established in 40 CFR part 85 and part 86. EPA expects the following provisions from 40 CFR part 1068 to not involve a substantive change for heavy-duty highway engines and vehicles:

- Part 1068, subpart A, describes how EPA handles confidential information, how the Administrator may delegate decision-making within the agency, how EPA may enter manufacturers' facilities for inspections, what information manufacturers must submit to EPA, how manufacturers are required to use good engineering judgment related to certification, and how EPA may require testing or perform testing. There is also a description of labeling requirements that apply uniformly for different types of engines/equipment.

- The prohibited acts, penalties, injunction provisions, and related requirements of 40 CFR 1068.101 and 1068.125 correspond to what is specified in Clean Air Act sections 203 through 207 (also see section 213(d)).

- 40 CFR 1068.103 describes how a certificate of conformity applies on a model-year basis. With the exception of the stockpiling provisions in paragraph (g), as described below, these provisions generally mirror what already applies for heavy-duty highway engines.

- 40 CFR 1068.120 describes requirements that apply for rebuilding engines. This includes more detailed provisions describing how the rebuild requirements apply for cases involving a used engine to replace a certified engine.

- 40 CFR part 1068, subpart F, describes procedural requirements for voluntary and mandatory recalls. As noted below, EPA is modifying these regulations to eliminate a few instances where the part 1068 provisions differ from what is specified in 40 CFR part 86, subpart S.

- 40 CFR part 1068, subpart G, describes how EPA would hold a hearing to consider a manufacturer's appeal of an adverse compliance decision from EPA. These procedures apply for penalties associated with violations of the prohibited acts, recall, nonconformance penalties, and generally for decisions related to certification. As noted below, EPA is migrating these procedures from 40 CFR part 86, including an effort to align with EPA-wide regulations that apply in the case of a formal hearing.

EPA is adopting a requirement for manufacturers to comply with the defect-reporting provisions in 40 CFR 1068.501. Defect reporting under 40 CFR 1068.501 involves a more detailed

approach for manufacturers to track possible defects and establishes thresholds to define when manufacturers must perform an investigation to determine an actual rate of emission-related defects. These thresholds are scaled according to production volumes, which allows us to adopt a uniform protocol for everything from locomotives to lawn and garden equipment. Manufacturers that also produce nonroad engines have already been following this protocol for several years. These defect-reporting requirements are also similar to the rules that apply in California.

40 CFR part 1068 includes a definition of "engine" to clarify that an engine becomes subject to certification requirements when a crankshaft is installed in an engine block. At that point, a manufacturer may not ship the engine unless it is covered by a certificate of conformity or an exemption. Most manufacturers have opted into this definition of "engine" as part of the replacement engine exemption as specified in 40 CFR 85.1714. We are making this mandatory for all manufacturers. A related provision is the definition of "date of manufacture," which we use to establish that an engine's model year is also based on the date of crankshaft installation. To address the concern that engine manufacturers might install a large number of crankshafts before new emission standards start to apply as a means of circumventing those standards, we state in 40 CFR 1068.103(g) that manufacturers must follow their normal production plans and schedules for building engines in anticipation of new emission standards. In addition to that broad principle, we state that we will consider engines to be subject to the standards for the new model year if engine assembly is not complete within 30 days after the end of the model year with the less stringent standards.

40 CFR part 1068 also includes provisions related to vehicle manufacturers that install certified engines. EPA states in 40 CFR 1068.105(b) that vehicle manufacturers are in violation of the tampering prohibition if they do not follow the engine manufacturers' emission-related installation instructions, which we approve as part of the certification process.

40 CFR part 1068 also establishes that vehicles have a model year and that installing certified engines includes a requirement that the engine be certified to emission standards corresponding to the vehicle's model year. An exception to allow for normal production and

build schedules is described in 40 CFR 1068.105(a). This "normal-inventory" allowance is intended to allow for installation of previous-tier engines that are produced under a valid certificate by the engine manufacturer shortly before the new emission standards start to apply. Going beyond normal inventory is considered to be "stockpiling." Stockpiling such engines will be considered an unlawful circumvention of the new emission standards. The range of companies and production practices is much narrower for heavy-duty highway engines and vehicles than for nonroad engines and equipment. EPA is therefore finalizing the proposed additional specifications to define or constrain engine-installation schedules that will be considered to fall within normal-inventory practices. In particular, vehicle manufacturers must follow their normal production schedules to use up their supply of "previous-tier" engines once new emission standards start to apply; the regulation further specifies that this allowance may not extend beyond three months into the year in which new standards apply. For any subsequent installation of previous-tier engines, EPA requires that vehicle manufacturers get EPA approval based on a demonstration that the excess inventory is a result of unforeseeable circumstances rather than circumvention of emission standards. EPA approval in those circumstances will be limited to a maximum of 50 engines to be installed for up to three additional months for a single vehicle manufacturer.

We are finalizing these stockpiling provisions, although we received two comments that supported changes from the proposal. Daimler suggested a greater allowance of 1000 or more engines meeting the earlier tier of standards to correspond to prevailing production volumes. This comment appears to reflect an expectation that engine manufacturers would continue to produce these previous-tier engines after the new emission standards have started to apply; however, this is not the case. The inventory allowance is focused on vehicle manufacturers using up their normal inventories of engines that were built before the change in emission standards over some number of months into the New Year. Even high-volume vehicle manufacturers should not be buying large quantities of engines shortly before a change in emission standard. The inventory allowance rather allows for vehicle manufacturers to prudently plan to make a reasonable transition to the new

engines in the months following the point at which the standards start to apply.

Gillig also commented on the stockpiling provisions, advocating a June 30 date for using up their inventory of previous-tier engines. Their production schedule typically involves building a single bus in a day, with the transition to new standards depending on engine manufacturers to provide compliant engines in a timely manner. The proposed allowance was intended to accommodate current business practices that involved using up normal inventory of previous-tier engines within three months after new standards start to apply, with a possible extension to six months if the manufacturer needs additional time to use up the last few of its normal inventory of previous-tier engines. We believe this approach is consistent with Gillig's recommendation.

EPA considered applying 40 CFR part 1068 broadly. It is relatively straightforward to apply the provisions of this part to all engines subject to the criteria emission standards in 40 CFR part 86, subpart A, and the associated vehicles. Manufacturers of comparable nonroad engines are already subject to all these provisions. However, highway motorcycles and Class 2b and 3 heavy-duty vehicles subject to criteria emission standards under 40 CFR part 86, subpart S, are covered by a somewhat different compliance program. EPA is therefore applying only the hearing procedures from 40 CFR part 1068 for highway motorcycles, light-duty vehicles, light-duty trucks, medium-duty passenger vehicles, and chassis-certified Class 2b and 3 heavy-duty vehicles. See Section XIII.D.(1) for a description of the hearing procedures from 40 CFR part 1068.

Note that EPA is amending 40 CFR 85.1701 to specify that the exemption provisions of 40 CFR part 85, subpart R, apply to heavy-duty engines subject to regulation under 40 CFR part 86, subpart A. This is intended to limit the scope of this provision so that it does not apply for Class 2b and 3 heavy-duty vehicles subject to standards under 40 CFR part 86, subpart S. This change corrects an inadvertently broad reference to heavy-duty vehicles in 40 CFR 85.1701.

B. Amendments Affecting Glider Vehicles and Glider Kits

(1) Background

EPA proposed several amendments related to both criteria pollutant and GHG emissions from glider vehicles, as well as related provisions for glider

kits.⁹⁸⁰ With respect to criteria pollutant emissions, EPA proposed that as of January 1, 2018, most donor engines installed in glider vehicles would have to meet criteria pollutant standards corresponding to the year of assembly of the glider vehicle. This would amend the provision allowing donor engines to meet the standards for the year of the engine. 40 CFR 1037.150(j). EPA further solicited comment on an earlier effective date for this provision. 80 FR 40529.

With respect to GHG emissions, EPA proposed that all glider vehicles (whether produced by large or small manufacturers) meet the Phase 2 vehicle standards (which, among other things, would entail glider kit manufacturers generating fuel maps for each engine that would be used). This would remove a transition provision from the Phase 1 rules which allowed glider vehicles to use engines not certified to the Phase 1 standards. 40 CFR 1037.150(j). Glider vehicles produced by large manufacturers are presently subject to the Phase 1 vehicle standards, but those produced by small manufacturers are not. 40 CFR 1037.150(c). Put a different way, the combination of these two provisions means that non-small businesses could use pre-2013 engines in glider vehicles, but were required to meet (and certify to) the Phase 1 GHG vehicle standards. EPA proposed to require all glider vehicles to meet the applicable GHG standards as of January 1, 2018. See generally 80 FR 40528.

In the March, 2016 Notice of Data Availability, EPA solicited further comment on possible exceptions to the proposal.⁹⁸¹ Specifically, EPA solicited comment with respect to engines meeting 2010 criteria pollutant standards, and for engines still within their original regulatory useful life. 81 FR 10826.⁹⁸²

EPA received many comments from manufacturers of both glider kits and glider vehicles, many comments from manufacturers of engines meeting current criteria pollutant standards and dealers selling trucks containing those

compliant engines, and comments from the NGO community and from CARB. Engine and vehicle manufacturers took opposing positions. Some supported the proposed approach, and urged an earlier effective date to avoid a pre-buy of glider vehicles with highly polluting engines. Others stated that the proposed provisions exceeded EPA's authority to set emission standards for new engines and new vehicles, in addition to objecting to the proposed provisions as a matter of policy. See Section I.E.1 of this document and RTC Section 14.2. Some of the comments helped EPA target flexibility for glider vehicles that serve arguably legitimate purposes (such as reclaiming relatively new powertrains from vehicles chassis that fail prematurely), without causing substantial adverse environmental impacts. All of these comments are fully summarized and responded to in RTC Section 14.2. We set out here the actions we are taking in this Phase 2 rule, and then explain the basis for those actions.

(2) Overview of Final Rule Provisions for Glider Kits and Glider Vehicles

We are finalizing the proposed glider-related provisions but have made several revisions in recognition of the differences between glider vehicles produced to avoid the 2010 criteria pollutant emission standards and those manufactured for other more legitimate purposes. The provisions being finalized are intended to allow a transition to a long-term program in which manufacture of glider vehicles better reflects the original reason manufacturers began to offer these vehicles—to allow the reuse of relatively new powertrains from damaged vehicles.

Under the provisions being finalized for the long-term program, all glider vehicles will need to be covered by both vehicle and engine certificates. The vehicle certificate will require compliance with the GHG vehicle standards of 40 CFR part 1037. The engine certificate will require compliance with the GHG engine standards of 40 CFR part 1036, plus the criteria pollutant standards of 40 CFR part 86. Used/rebuilt/remanufactured engines may be installed in the glider vehicles without meeting standards for the year of glider vehicle assembly, provided the engines are within their regulatory useful life (or meet similar criteria). These engines would still need to meet criteria pollutant standards corresponding to the year of the engine.

EPA is also finalizing a transitional program that will allow glider vehicle manufacturers additional flexibility. The first step allows each

⁹⁸⁰ Glider vehicles are motor vehicles produced to accept rebuilt engines (or other used engines) along with used axles and/or transmissions. The common commercial term "glider kit" is used here primarily to refer to a chassis into which the used/rebuilt engine is installed. See Figure I-1 in section I.E.1 of this Preamble, showing a picture of a glider kit.

⁹⁸¹ The NODA requested comment on an EPA memorandum "Legal Memorandum Discussing Issues Pertaining to Trailers, Glider Vehicles, and Glider Kits under the Clean Air Act", February 2016, EPA-HQ-OAR-2014-0827-1627, 81 FR 10826.

⁹⁸² Glider vehicles and glider kits are exempt from NHTSA's Phase 1 fuel consumption standards. NHTSA did not propose revisions specific to glider vehicles in this rulemaking.

manufacturer's combined production of glider kits and glider vehicles with higher polluting engines to be at the manufacturer's highest annual production of glider kits and glider vehicles for any year from 2010 to 2014.⁹⁸³ Any glider vehicles produced in greater volumes would need to meet the engine standards corresponding to the year of the assembly of the glider vehicle. With respect to GHG standards, all vehicles within this allowance will remain subject to the existing Phase 1 requirements for both engines and vehicles, so that small manufacturers would still be exempt from these provisions up to the allowance. Any glider kits and glider vehicles produced beyond this allowance will be subject to all requirements applicable to new engines and new vehicles for MY 2017. Other than the 2017 production limit, EPA will continue the Phase 1 approach until January 1, 2018. This allows small businesses to produce glider kits and glider vehicles up to the production limit without new constraints. Large manufacturers producing complete glider vehicles remain subject to the 40 CFR part 1037 GHG vehicle standards, as they have been since the start of Phase 1. However large manufacturers may provide exempted glider kits to small businesses during this time frame.

Effective January 1, 2018, the long-term program begins generally, but with certain transitional flexibilities. In other words, except for the following allowances, glider vehicles will need to comply with the long-term program. The exceptions are:

- Small businesses may produce a limited number of glider vehicles without meeting either the engine or vehicle standards of the long-term program. Larger vehicle manufacturers may provide glider kits to these small businesses without the assembled vehicle meeting the applicable vehicle standards. This number is limited to the small vehicle manufacturer's highest annual production volume in 2010 through 2014 or 300, whichever is less.
- Model year 2010 and later engines are not required to meet the Phase 1 GHG engine standards.
- Used/rebuilt/remanufactured engines may be installed in the glider vehicles without meeting standards for the year of glider vehicle assembly, provided the engines are within their regulatory useful life (this provision

continues from the transitional program).

These 2018 allowances mostly continue after 2020, but effective January 1, 2021, all glider vehicles will need to meet the Phase 2 GHG vehicle standards. This means that large manufacturers providing glider kits to small manufacturers will need to meet the GHG vehicle standards for the completed vehicle (pursuant to the delegated assembly provisions), or ship the glider kit to the final glider vehicle manufacturer pursuant to the incomplete vehicle provisions (where the final glider vehicle manufacturer would be the certificate holder).

EPA is thus discontinuing both 40 CFR 1037.150(c) and (j) in this Phase 2 rulemaking. As finalized, the Phase 2 regulations will therefore generally treat glider vehicles the same as other new vehicles.⁹⁸⁴ As a result, glider vehicles must be certified to the Phase 2 vehicle GHG standards, which (among other things) require a fuel map for the actual engine in order to run GEM. In other words, manufacturers producing glider kits need to meet the applicable GHG vehicle standards and, as part of their compliance demonstration, need to have a fuel map for each engine used. Alternatively, the final assembler could be the entity to obtain the certificate, provided it had substantial control of the overall emissions performance of the completed vehicle. In either case, manufacturers unable to obtain a fuel map for an engine may ask to use a default map, consistent with good engineering judgment.

EPA is also providing a limited allowance for small business manufacturers as described in 40 CFR 1037.150(t), and also providing a generally-applicable allowance that is conditioned on the age of the reused engine as described in 1037.635. See Section XIII.B.(4) below. EPA is also adopting new definitions of "glider vehicle" and "glider kit" in 40 CFR 1037.801 that are generally consistent with the common understanding of these terms as meaning new chassis with a rebuilt or other used engine and new chassis designed to accept a rebuilt or other used engine/powertrain. EPA is also clarifying its requirements for certification and revising its definitions for glider manufacturers, as described below, to ensure that affected manufacturers understand their responsibilities under the regulations.

It is important to emphasize that EPA is not banning gliders. Rather, as described below, EPA is requiring that glider vehicles meet the standards that all other new trucks are required to meet, unless eligible for certain limited exemptions that provide flexibility for small businesses and for certain other specific applications. Moreover, the provisions being finalized are more flexible than those proposed, but focus the additional flexibility on vehicles using relatively clean engines, and on engines within their regulatory useful life, consistent with the original purpose of glider kits and vehicles.⁹⁸⁵

EPA proposed to begin these requirements January 1, 2018, but requested comment on beginning the requirements sooner. Since the NPRM, production of gliders has surged and now likely exceeds 10,000 per year. We are concerned that by finalizing restrictions for 2018 in this rule we risk causing a pre-buy scenario where production surges further in 2017. This would be both very harmful to the environment and disruptive to the market. To avoid these problems and to ensure a smoother transition, we are finalizing a glider kit and glider vehicle production limit for calendar year 2017 for glider vehicles using high polluting engines. The allowable production is based on past sales for all large and small manufacturers. Specifically, each manufacturer's combined 2017 production of glider kits and glider vehicles using high polluting engines will be capped at the manufacturer's highest annual production of glider kits and glider vehicles for any year from 2010 to 2014. All vehicles within this allowance will remain subject to the existing Phase 1 GHG provisions as they presently apply. Any glider kits or glider vehicles produced beyond this allowance will be subject to all requirements applicable to new engines and new vehicles for MY 2017.

(3) Impacts of Current Glider Market

Current standards for NO_x and PM (which began in 2007 and took full effect in 2010) are at least 90 percent lower than the most stringent previously applicable standards, so the NO_x and PM emissions of any glider vehicles using pre-2007 engines are at least ten times higher than emissions from equivalent vehicles being produced with brand new engines.⁹⁸⁶ However,

⁹⁸³ Although discussed here as a limit on the number of glider vehicles that may be produced, these provisions are actually exemptions for manufacturers from the more generally applicable restrictions on the production of glider vehicles, as the following sentence in the text above makes clear.

⁹⁸⁴ EPA has structured these regulations for glider vehicles to lay out a general requirement that treats glider vehicles (and the engines installed in them) the same as other new vehicles (and new engines), but also includes several exemptions from this general requirement.

⁹⁸⁵ Although discussed here as a limit on the number of glider vehicles that may be produced, these provisions are actually exemptions for manufacturers from the more generally applicable restrictions on the production of glider vehicles.

⁹⁸⁶ The NO_x and PM standards for MY 2007 and later engines are 0.20 g/hp-hr and 0.01 g/hp-hr,

most gliders being produced today use engines originally manufactured before 2002.⁹⁸⁷ Since these pre-2002 engines lack both EGR and exhaust aftertreatment, they would have NO_x and PM emissions 20–40 times higher than current engines. If miscalibrated, emissions could be even higher. Thus, each glider vehicle using an older engine that is purchased instead of a new vehicle with a current MY engine results in significantly higher in-use emissions of air pollutants associated with a host of adverse human health effects, including premature mortality (see Section VIII above).

These emission impacts have been compounded by the increasing sales of these vehicles. Estimates provided to EPA indicate that production of glider vehicles has increased by an order of magnitude from what it was in the 2004–2006 time frame—from a few hundred each year to thousands.⁹⁸⁸ Glider vehicle production is not currently being reported to EPA, but EPA estimates that current production is close to 10,000 each year based on comments—including comments from manufacturers of glider vehicles. While the few hundred glider vehicles produced annually in the 2004–2006 timeframe may have been produced for arguably legitimate purposes, such as salvaging powertrains from vehicles otherwise destroyed in crashes, EPA believes (as did many commenters) that the more than tenfold increase in glider kit production since the MY 2007 criteria pollutant emission standards took effect reflects an attempt to avoid these more stringent standards and (ultimately) the Clean Air Act.

At proposal, EPA estimated the environmental impact of 5,000 glider vehicles per year, which would be roughly 2 percent of the Class 8 vehicles manufactured annually.⁹⁸⁹ We estimated that at that rate, these gliders could account for as much as one-half of total NO_x and PM emissions from all

new Class 8 vehicles. Several commenters supported EPA's assessment of the environmental impacts of glider vehicles. Volvo suggested the impacts were even greater, estimating that 2014 glider sales were "on the order of 6,000" and that they emit twice as many tons of PM as the rest of the 2014 vehicles. In later supplemental comments, Volvo provided evidence that current sales have grown to 10,000 or more per year. Even some commenters opposing EPA's proposal acknowledged that glider sales are now over 10,000 units annually. No commenters disagreed with EPA's previous (understated) assessment of NO_x and PM impacts.

For the final rule, EPA has updated its analysis of the environmental impacts of gliders. The updated analysis used the same emissions modeling tool used to estimate the other emissions impacts of the rule, described in Section VII of the Preamble. The modeling of gliders assumed annual glider sales of 10,000 for 2015 and later, consistent with the comments received on the proposal. The modeling also assumed that these gliders emit at the level equivalent to the engines meeting the MY 1998–2001 standards, since most glider vehicles currently being produced use remanufactured engines of this vintage, and projects them to have the same usage patterns/lifetimes as similar new vehicles. (We did not attempt to account for any miscalibration of these engines). This analysis shows that without the new restrictions, glider vehicles on the road in 2025 would emit nearly 300,000 tons of NO_x and nearly 8,000 tons of PM annually. Although glider vehicles would make up only 5 percent of heavy-duty tractors on the road, their emissions would represent *about one third* of all NO_x and PM emissions from heavy-duty tractors in 2025. By restricting the number of glider vehicles with high polluting engines on the road, these excess PM and NO_x emissions will decrease dramatically, leading to substantial public health-related benefits. Put into monetary terms using PM-related benefit-per-ton values described in Section IX.H, the removal of all unrestricted glider vehicle emissions from the atmosphere would yield between \$6 to \$14 billion in benefits annually (2013\$). It is clear that removing even a fraction of these glider vehicles with high polluting engines from the road will yield substantial health-related benefits.

(4) EPA Engine Standards

EPA is thus amending its rules to generally require that glider vehicles produced on or after January 1, 2017 use

engines certified to the standards applicable to the calendar year in which assembly of the glider vehicle is completed, with an exception in 2017 that provides a larger number of glider vehicles under the transitional production allowance. (Other exceptions to this general requirement are discussed later). This requirement applies to all pollutants, and thus encompasses criteria pollutant standards as well as the separate GHG standards. Used or rebuilt engines may be used, as long as they have been certified to the same standards that apply for the calendar year of glider vehicle assembly. For example, if assembly of a glider vehicle is completed in calendar year 2020, the engine must generally meet standards applicable for MY 2020. (If the engine standards for model year 2020 are the same as for model years 2017 through 2019, then any model year 2017 or later engine may be used).

EPA is amending these rules because, with the advent in MY 2007 of more stringent HD diesel engine criteria pollutant standards, continuation of provisions allowing unlimited use of rebuilt and reused engines meeting much earlier MY criteria pollutant standards results in unnecessarily high in-use emissions. See Section XII.B.(3) above. As stated there, these emissions form an increasingly high percentage of the vehicular inventory for such dangerous pollutants as NO_x and diesel exhaust PM (a likely human carcinogen), all of which are associated with the most serious adverse health effects up to and including premature mortality. GHG emissions from these engines also are controllable. As more glider vehicles are produced, EPA believes these emissions should be controlled to the same levels as other new engines.

The older engines currently being used in most glider vehicles could be retrofitted with exhaust aftertreatment to meet current standards. However, the primary reason these engines have been used is because they do *not* include aftertreatment.⁹⁹⁰ Thus, we believe retrofitting these engines would not be a preferred path. The more likely compliance path would be to install a used 2010 or later engine, since such engines are presently available and it would be probably be much simpler and less expensive to use a 2010 engine than to retrofit an older engine to meet current standards. Manufacturers will

respectively. The standards for MY 2004 through 2006 engines were ten times these levels, and earlier standards were even higher.

⁹⁸⁷ See, e.g. <http://www.truckinginfo.com/article/story/2013/04/the-return-of-the-glider.aspx>, describing the engines used by a leading manufacturer of glider vehicles ("1999 to 2002-model diesels were known for reliability, longevity and good fuel mileage. Fitzgerald favors Detroit's 12.7-liter Series 60 *from that era*, but also installs pre-EGR 14-liter Cummins and 15-liter Caterpillar diesels. All are rebuilt . . .") (emphasis added). See also additional documentation of this point in RTC Section 14.2.

⁹⁸⁸ "Industry Characterization of Heavy Duty Glider Kits," MacKay & Company, September 30, 2013.

⁹⁸⁹ Frequently Asked Questions about Heavy-Duty "Glider Vehicles" and "Glider Kits," EPA-420-F-15-904, July 2015.

⁹⁹⁰ <http://www.truckinginfo.com/article/story/2013/04/the-return-of-the-glider.aspx>, accessed July 16, 2016.

likely also seek to qualify under other flexibilities provided in the Final Rule.

Recognizing that the environmental impacts of gliders using newer engines will generally be much smaller, EPA requested comment on whether we should treat such gliders differently than gliders using older engines. 80 FR 40528; 81 FR 10826. Based on comments received on the NODA, EPA is finalizing additional flexibilities for newer engines and for engines with very low mileage. More specifically, EPA will allow engines meeting any of the following criteria to be used in glider vehicles without meeting current engine standards for either criteria pollutants or GHGs:

(1) Engines still within their original useful life in terms of both miles and years.

(2) Engines of any age with less than 100,000 miles of engine operation, provided the engines' miles are properly documented.

(3) Engines less than three years old with any number of accumulated miles of engine operation.⁹⁹¹

Engines covered by these three criteria are consistent with the original intended use of glider kits—the salvaging of relatively new powertrains from vehicle chassis that have been damaged or have otherwise failed prematurely. Most of these engines would be covered by the first criterion. While nearly all of these engines would be model year 2010 or later, this criterion would theoretically allow use of model year 2008 or 2009 engines in calendar years before 2020.

Nevertheless, such engines would have been certified to the same PM standards as the 2010 engines, and would likely have NO_x emissions at or below 1.2 g/hp-hr (*i.e.*, the typical certification level for engines of that vintage). EPA is adopting the second criterion to address very rare cases that were identified in comments in which annual VMT is so low that engines would not reach

100,000 miles within ten years (the useful life in years). These engines could be higher emitting, but would necessarily be in applications with very low usage, such as a small town fire truck. As such, the total emissions from such vehicles would be very small. The third criterion would address other rare cases such as where an engine is just outside the useful life in miles, or the miles cannot be determined. These engines would necessarily be model year 2015 or later, and would thus all meet the 2010 standards. Considered together, this additional flexibility would have little adverse emission impact because there would be relatively few engines covered by these exceptions and the vast majority would be 2010 or later.

Several commenters supported allowing unlimited production of glider vehicles if they use engines certified to 2010 or later NO_x and PM standards, without regard to whether the engines were still within their useful life. EPA sees merit in this concept, but is concerned that it may not be appropriate in perpetuity. Obviously, reuse of engines originally certified to the 2010 standards for criteria pollutants would not have the same adverse environmental impacts as the current practice of reusing pre-2002 engines that have NO_x and PM emissions 20–40 times higher than current engines (or using post-2002 but pre-2007 engines, which remain an order of magnitude more polluting). However, they would not necessarily be as clean for GHG or criteria pollutants as brand new engines with all new aftertreatment components. The Phase 1 and Phase 2 engine standards mean that brand new engines will have lower GHG emissions than pre-Phase 1 engines. See RIA Chapter 8 and RTC Section 14.2. And used 2010 aftertreatment components may be less effective at reducing NO_x or PM than when new. Moreover, EPA has been petitioned to adopt more stringent NO_x and/or PM standards in the future. See Section I.F.(1) above. Thus, while using 2010 engines in glider vehicles would greatly reduce the most serious concerns about NO_x and PM emissions relative to current gliders, it would not eliminate all adverse environmental impacts.

To balance these factors, EPA is finalizing an interim provision—a provision which may sunset if EPA adopts new more stringent NO_x or PM standards for heavy duty engines—that will treat gliders using MY 2010 and later engines the same as those using engines within their useful life. This would avoid most of the adverse impacts, especially for NO_x and PM.

Not requiring these engines to meet the latest GHG standards could have some impacts, but they would likely be small, especially if glider vehicle sales return to pre-2007 levels. EPA will continue to monitor sales patterns and may rescind this flexibility in a future rulemaking.

Several commenters expressed concern about the impact of the proposed changes on small businesses that produce glider vehicles. However, commenters opposing the proposed requirements/clarifications did not address the very significant adverse environmental impacts of the huge increase in glider vehicle production over the last several years. EPA recognized at the time of the proposal that production of a smaller number of other gliders by small manufacturers may be appropriate, at least as an interim allowance. 80 FR 40529. To allow this, EPA is adopting the proposed provision that will somewhat preserve the regulatory status quo for existing small businesses, allowing limited production using highly polluting engines based on recent sales. This means a limited number of glider vehicles produced by small businesses may use older rebuilt or used engines, provided those engines were certified to standards from the year of the engine's manufacture. (Note that beginning in MY 2021, these vehicles will have to meet the GHG vehicle standards, although they would not be required to meet current criteria pollutant standards.) For example, an existing small business that produced glider vehicles between 2010 and 2014, with a peak production of 200 in 2013, may produce up to 200 glider vehicles per year under without having to certify them to the GHG standards, or recertifying the engines to the now-applicable EPA standards for criteria pollutants (so long as the engine is certified to criteria pollutant standards for the year of its manufacture). To be eligible for this provision, 40 CFR 1037.150(t), the regulation specifies that no small entity may produce more than 300 glider vehicles (including any glider kits it sells to another assembler) using the older engines in any given model year without recertifying the engines to current EPA standards. EPA believes that this level reflects the upper end of the range of production that occurred before significant avoidance of the 2007 criteria pollutant standards began. EPA believes that, given this relief combined with the other changes being made into the final regulations, any small businesses that have been focused on producing gliders for legitimate purposes will not be significantly

⁹⁹¹ EPA's authority to craft different provisions for engines within their useful life, and provisions allowing continued production of glider vehicles using pre-2010 engines comes from CAA authority to consider costs under section 202(a)(2) and 202(a)(3)(D), as well as the broad authority in section 202(a)(3)(D) over engine rebuilding. Thus, many of these flexibilities are tailored to avoid significant and disproportionate economic impacts on small business glider vehicle manufacturers by allowing most small businesses to continue to produce glider vehicles consistent with current levels of production, consistent with the recommendations of the Small Business Advocacy Review panel. See RIA section 12.7.3. Allowing continued use of engines within their original useful life is also consistent with one purpose of the engine rebuilding provisions, which is to find some legitimate means of salvaging heavy duty engines without backsliding from those engines' original certified condition. See 62 FR 54702.

impacted by the new requirements, since they can use donor engines within their regulatory useful life for either age or mileage. See generally RIA Chapter 12.7.3. Only those small businesses that have significantly increased production to create new trucks to avoid the 2010 NO_x and PM standards will have their sales significantly restricted.

This small business flexibility is intended for small entities for whom glider production is a substantial portion of their revenue to allow them to transition to the long-term program where they would generally install newer cleaner engines. (We recognize that the final regulations will allow some small businesses to produce a limited number of glider vehicles with higher polluting engines as a side business, but do not expect these manufacturers to produce very many glider vehicles.) We intend to monitor its use and may place additional restriction on this flexibility in the future consistent with this intended purpose.

We are also adopting provisions to facilitate a smoother transition for small businesses that assemble glider vehicles from glider kits produced by larger manufacturers. Although the long-term program will require vehicle certificates for glider vehicles produced by small manufacturers using exempted engines, we are delaying the requirement for a vehicle certificate until 2021 for these glider vehicles. This means the large glider kit manufacturers may continue the Phase 1 allowance to sell exempted glider kits (*i.e.*, uncertified glider kits) to small assemblers as previously allowed under Phase 1 by 40 CFR 1037.620. However, beginning January 1, 2021, each glider kit sold to small assemblers will need to have a vehicle certificate the same as is required for other new Phase 1 and Phase 2 glider vehicles.

Although we are allowing this flexibility for glider kit manufacturers, they remain responsible to take reasonable steps to ensure that their glider kits are not used to produce complete vehicles in violation of the regulations. Most importantly, the glider kit manufacturer must comply fully with the requirements of 40 CFR 1037.622, which specifies certain minimum requirements for shipping uncertified incomplete vehicles. If the glider kit manufacturer is the certificate holder, then the glider kit manufacturer would have to comply with the delegated assembly requirements of 40 CFR 1037.621. See 40 CFR 1037.635(d)(3). In addition, we would expect manufacturers of glider kits to have records to verify that the vehicle assembler to whom they are shipping an

uncertified glider kit (which would remain permissible under Phase 1) is aware of the regulatory requirements and is eligible to produce glider vehicles with older engines that do not meet current criteria pollutant standards (*i.e.*, is a small business within the volume limit, or is using engines within their regulatory useful life). For any assembler that is purchasing more than one hundred glider kits in a year from a kit manufacturer, the kit manufacturer should verify that they are not exceeding their allotted number. For smaller assemblers, it may be sufficient to verify that they are not requesting more glider kits from that kit manufacturer than they purchased in any year from 2010 to 2014. Failure to comply with these requirements, or shipping glider kits to an ineligible manufacturer which produces glider vehicles with non-compliant engines, may void the exemption granted pursuant to 40 CFR 1037.621 or 1037.622. For example, as explained in Section I.E.(1)(d) above, supplying glider kits to an ineligible manufacturer could result in causing a violation of the Act, and thus is itself a prohibited act under section 203(a)(1).

Finally, we are adopting a new provision in 40 CFR 1036.150(o) that would allow an engine manufacturer to modify a used engine to be identical to a previously certified configuration. (This is similar to the allowance in 40 CFR 1068.201(i).) This allows the manufacturer to include the used engine in an existing certificate for the purposes of complying with the requirement to meet current standards when installing an engine into a glider vehicle. For example, if an engine manufacture modified a used 2009 engine to be identical to a certified 2017 engine, we would allow the 2009 engine to be covered by the 2017 certificate, which would allow it to be installed into a glider vehicle without restriction.

(5) Lead Time for Amended Provisions

Other than the production volume provision discussed at the beginning of this Section XIII.B, the requirement for gliders to meet engine and vehicle standards applicable to other new vehicles and engines do not take effect before January 1, 2018. With respect to the criteria pollutant engine standards, EPA believes this provides sufficient time to “permit the development and application of the requisite control measures” (CAA section 202(a)(3)(D)) because compliant engines are available today, although manufacturers will need several months to change business practices to comply.

Some commenters argued that because some of these requirements relate to criteria pollutant standards, EPA must provide at least four years lead time pursuant to section 202(a)(3)(C) of the Clean Air Act. EPA addresses these comments in Section I.E.(1) and in the RTC Sections 1.3.1 and 14.2. With respect to the vehicle standards, EPA notes that the requirements already apply for vehicles not produced by small businesses. EPA believes that delaying the applicability of the vehicle standards to small businesses until 2021 when Phase 2 takes effect provides ample time to comply with vehicle GHG standards. See CAA section 202(a)(2) (standards to provide lead time sufficient to allow for “development and application of the requisite technology”).

(6) Legal Authority and Definitions Under the Clean Air Act

With respect to statutory authority for the criteria pollutant standards under the Clean Air Act, EPA notes first that it has broad authority to control all pollutant emissions from “any” rebuilt heavy duty engines (including engines beyond their statutory useful life). See CAA section 202(a)(3)(D). EPA is to give “appropriate” consideration to issues of cost, energy, and safety in developing such standards, and to provide necessary lead time to implement those standards. If a used engine is placed in a new glider vehicle, the engine will be considered a “new motor vehicle engine” because it is being used in a new motor vehicle. See CAA section 216(3) and Section I.E.(1). With respect to the vehicle-based GHG standards, there is no question that the completed glider vehicle is a “motor vehicle” under the Clean Air Act. Some commenters have questioned whether a glider kit (without an engine) is a motor vehicle. However, EPA considers glider kits to be incomplete motor vehicles and entities manufacturing gliders to be manufacturers of those vehicles, and EPA has the authority to regulate incomplete motor vehicles and manufacturers thereof, including un-motorized chassis. See Section I.E.(1)

Under the CAA, it is also important that “new” is determined based on legal title and does not consider prior use. Thus, glider vehicles that have a new vehicle identification number (VIN) and new title are considered to be “new motor vehicles” even if they incorporate previously used components. It is also the case that under the Clean Air Act, EPA does not consider the fact that a vehicle retained the VIN of the donor vehicle from which the engine was obtained determinative of whether or

not the vehicle is new. See Section I.E.(1) (responding to comment on this point).

The CAA also defines “manufacturer” to include any person who assembles new motor vehicles. As proposed, EPA is revising its regulatory definitions of these terms in 40 CFR 1036.801 and 1037.801 to more clearly reflect these aspects of the CAA definitions. The revised definitions make clear that:

- New glider kits are “new motor vehicles.” Manufacturers therefor must certify to the Phase 2 vehicle standards unless they are selling the glider kit to a secondary manufacturer that has its own certificate.
- Previously used engines installed into glider kits are “new motor vehicle engines.”
- Any person who completes assembly of a glider vehicle is a “manufacturer” thereof.

EPA also notes that under existing regulations, glider kit assemblers (*i.e.* entities that assemble the glider vehicle by adding the donor engine to the kit) are already considered to be secondary vehicle manufacturers, who may receive incomplete vehicles (such as glider kits) from OEMs if they have a valid certificate or exemption (see 40 CFR 1037.622). Secondary vehicle manufacturers may also receive certified glider kits to complete in a delegated assembly agreement (see 40 CFR 1037.621).

To further clarify that EPA considers both glider kits and completed glider vehicles to be motor vehicles, EPA is adding a clarification to our definition of “motor vehicle” in 40 CFR 85.1703 regarding vehicles such as gliders that clearly are intended for use on highways, consistent with the CAA definition of “motor vehicle” in CAA section 216(2). The regulatory definition previously contained a provision stating that vehicles lacking certain safety features required by state or federal law are not “motor vehicles.” EPA recognized that this caveat needed a proper context: Is the safety feature one that would prevent operation on highways? See 80 FR 40529. If not, absence of that feature does not result in the vehicle being other than a motor vehicle. The amendment will consequently make clear that vehicles that are clearly intended for operation on highways are motor vehicles, even if they do not have every safety feature. This clarifying provision takes effect with this rule.

We note that NHTSA and EPA have separate definitions for motor vehicles under their separate statutory authorities. As such, EPA’s determination of how its statute and

regulations apply to glider kits and glider vehicles has no bearing on how NHTSA may apply its safety authority with regard to them.

(7) Summary of the Requirements for Glider Vehicles

The provisions being finalized are intended to allow a transition to a long-term program in which use of glider kits is permissible consistent with the original reason manufacturers began to offer glider kits—to allow the reuse of relatively new powertrains from damaged vehicles. The long-term program as well as the transitional program are summarized below.

(a) Long-Term Program for Gliders

Ultimately all gliders will need to be covered by both vehicle and engine certificates. The vehicle certificate will require compliance with the GHG vehicle standards of 40 CFR part 1037. The engine certificate will require compliance with the GHG engine standards of 40 CFR part 1036, plus the criteria pollutant standards of 40 CFR part 86. Used/rebuilt engines may be installed in the glider vehicles, provided (1) they meet all standards applicable to the year in which the assembly of the glider vehicle is completed; or (2) meet all standards applicable to the year in which the engine was originally manufactured and also meet one of the following criteria:

- The engine is still within its original useful life in terms of both miles and years.
- The engine has less than 100,000 miles of engine operation.
- The engine is less than three years old.

In most of these cases, the glider vehicles will need to have a vehicle certificate demonstrating compliance with the vehicle GHG standards that apply for the year of assembly. However, in the case of engines with less than 100,000 miles, glider vehicles conforming to the vehicle configuration of the donor vehicle do not need to be recertified to current vehicle standards.

(b) Transitional Program for Gliders

For calendar year 2017, each manufacturer’s combined production of glider kits and glider vehicles will be capped at the manufacturer’s highest annual production of glider kits and glider vehicles for any year from 2010 to 2014. All vehicles within this allowance will remain subject to the existing Phase 1 provisions, including its exemptions. Any glider kits or glider vehicles produced beyond this allowance will be subject to the long-term program.

Other than the 2017 production limit, EPA will continue the Phase 1 approach until January 1, 2018. This allows small businesses to produce glider vehicles up to the allowance without other new constraints before 2018. Large manufacturers producing complete glider vehicles remain subject to the 40 CFR part 1037 GHG vehicle standards, as they have been since the start of Phase 1. However large manufacturers may provide exempted glider kits to small businesses during this time frame. Other than the 2017 production limit, EPA will continue the Phase 1 approach until January 1, 2018. This allows small businesses to produce glider vehicles up to the cap without other new constraints before 2018. Large manufacturers producing complete glider vehicles remain subject to the 40 CFR part 1037 GHG vehicle standards, as they have been since the start of Phase 1. However large manufacturers may provide exempted glider kits to small businesses during this time frame.

Effective January 1, 2018, the permissible number of glider vehicles that may be produced without meeting the long-term program will be limited to two specific exceptions. The exceptions are:

- Small businesses may produce a limited number of glider vehicles without meeting either the engine or vehicle standards of the long-term program. Larger vehicle manufacturers may provide glider kits to these small businesses without meeting the applicable vehicle standards. This number is limited to the small manufacturer’s highest annual production volume in 2010 through 2014 or 300, whichever is less.
- Model year 2010 and later engines are not required to meet the Phase 1 GHG engine standards.

These 2018 allowances mostly continue after 2020, but the following change takes effect January 1, 2021:

- All glider kits provided by large manufacturers (including to small manufacturers or for use with 2010 engines) must meet the vehicle standards for the completed vehicle.

EPA is not establishing an end to these transitional provisions at this time. We intend to monitor this industry and will reevaluate the appropriateness of these provisions in the future.

C. Applying the General Compliance Provisions of 40 CFR Part 1068 to Light-Duty Vehicles, Light-Duty Trucks, Chassis-Certified Class 2_B and 3 Heavy-Duty Vehicles and Highway Motorcycles

As described above, EPA is applying all the general compliance provisions of 40 CFR part 1068 to heavy-duty engines

and vehicles subject to 40 CFR parts 1036 and 1037. EPA is also applying the amended hearing procedures from 40 CFR part 1068 to highway motorcycles and all vehicles subject to standards under 40 CFR part 86, subpart S. However, based on comments, we are not finalizing broader changes at this time.

Volvo objected to extending the defect-reporting provisions of 40 CFR part 1068 to heavy-duty engines and vehicles. They stated that they have a robust approach to defect-reporting that is largely consistent with what applies under 40 CFR part 1068 (in addition to complying with CARB's warranty-reporting requirements), but argued that it would be cost-prohibitive to comply nationwide with the new federal requirements. They commented that the higher reporting thresholds would lead to fewer reports. We understand and accept that there may be fewer defect reports; in fact, we count this as a positive development since industry and agency efforts toward documenting and addressing defects will be focused on cases that are worthy of greater attention. The defect threshold of 25 units under 40 CFR part 85 is not appropriate for the sales volumes associated with heavy-duty engines and vehicles.

Light-duty automotive manufacturers also objected to the mandatory migration of defect-reporting provisions to 40 CFR part 1068 for heavy-duty vehicles they produce, emphasizing that their light-duty and heavy-duty vehicles should be subject to the same defect-reporting protocol to reduce complexity and risk of error. Although we are not applying the 40 CFR part 1068 defect-reporting requirements to heavy-duty vehicles subject to the requirements of 40 CFR part 86, subpart S, we are applying them to all other heavy-duty vehicles produced by these manufacturers. As noted below, we plan to eventually migrate the defect-reporting provisions for all light-duty and heavy-duty vehicles to 40 CFR part 1068, and see no harm in doing so in steps. These manufacturers also expressed three more detailed concerns about defect reporting under 40 CFR part 1068: (1) Twice-annual investigation reports may show no defects, which would add a paperwork burden for no benefit, (2) the reporting period covers the full useful life, rather than just the first five years, which is the time when most defects appear, and (3) tying defect reporting to warranty claims may discourage extended warranties. The idea behind the investigation reports is that a high rate of possible defects may or may not be

associated with a substantial number of actual defects. The investigation reports are intended to address exactly that question. The burden arises only when the manufacturer has a high enough rate of possible defects to warrant further attention. We see no reason to disregard defect information between five years and the end of the useful life, since manufacturers are responsible for designing their products to last during that entire period. Specifying a shorter period would artificially and arbitrarily reduce the information available to reach a conclusion. If defects don't occur after five years, then there is no additional burden associated with the longer period. EPA does not take a position on the manufacturers' practices regarding extended warranties; however, we feel strongly that a manufacturer's confidence as expressed in an extended warranty should correspond with the same level of confidence in the engines (or components) working to control emissions for that same period.

EPA proposed to also apply the recall provisions from 40 CFR part 1068 for highway motorcycles and for all vehicles subject to standards under 40 CFR part 86, subpart S, and requested comment on applying the defect reporting from 40 CFR part 1068 for those same vehicles. Manufacturers objected to modifying the recall and defect-reporting provisions in this rulemaking. EPA is accordingly not finalizing these additional provisions; EPA intends rather to pursue these changes in a later rulemaking, which will allow both EPA and manufacturers and other stakeholders additional time to carefully consider the range of issues that may be involved. In particular, EPA anticipates the opportunity to apply some learning from the current focus on defeat devices, recall, and defect reporting in the effort to update the regulations.

Note that EPA is amending 40 CFR 85.1701 to specify that the exemption provisions apply to heavy-duty engines subject to regulation under 40 CFR part 86, subpart A. This is intended to limit the scope of this provision so that it does not apply for Class 2b and 3 heavy-duty vehicles subject to standards under 40 CFR part 86, subpart S. This change corrects an inadvertently broad reference to heavy-duty vehicles in 40 CFR 85.1701.

D. Amendments to General Compliance Provisions in 40 CFR Part 1068

The general compliance provisions in 40 CFR part 1068 apply broadly to many different types of engines and equipment. This section describes how

EPA is amending these procedures to make various corrections and adjustments.

(1) Hearing Procedures

EPA is updating and consolidating its regulations related to formal and informal hearings in 40 CFR part 1068, subpart G. This will allow us to rely on a single set of regulations for all the different categories of vehicles, engines, and equipment that are subject to emission standards. EPA also made an effort to write these regulations for improved readability.

The hearing procedures specified in 40 CFR part 1068 apply to the various categories of nonroad engines and equipment (along with the other provisions of part 1068). EPA is in these rules applying these hearing procedures also to heavy-duty highway engines, light-duty motor vehicles, and highway motorcycles. EPA believes there is no reason to treat any of these sectors differently regarding hearing procedures. Automotive and engine manufacturers expressed broad concerns about migrating the hearing procedures in this rulemaking; however, the migration makes no substantive changes to established procedures, and addresses various administrative concerns as noted below.

EPA is adding an introductory section that provides an overview of requesting a hearing for all cases where a person or a company objects to an adverse decision by the agency. In certain circumstances, as spelled out in the regulations, a person or a company can request a hearing before a Presiding Officer. Statutory provisions require formal hearing procedures for administrative enforcement actions seeking civil penalties. The Clean Air Act does not require a formal hearing for other agency decisions; EPA is therefore specifying that informal hearing procedures apply for all such decisions.

The introductory section also adds detailed provisions describing the requirements for submitting information to the agency in a timely manner. These provisions accommodate current practices for electronic submission, distinguish between postal and courier delivery and provide separate requirements for shipments made from inside and outside the United States. The specified deadlines are generally based on the traditional approach of a postmark determining whether a submission is timely or not. Fax, email and courier shipments are similarly specified as needing to be sent by close of business on the day of the deadline. A different approach applies for shipments originating from outside the

United States. Because time in transit can vary dramatically, we are specifying that foreign shipments need to be received in our office by the specified deadline to be considered timely. Given the option to send documents by email or by fax, EPA expects this approach will not pose any disadvantage to anyone making an appeal from outside the United States.

EPA is replacing the current reference to 40 CFR 86.1853–01 for informal hearings with a full-text approach that captures this same material. EPA attempted to write these regulations in a way that does not change the underlying hearing protocol.

The regulations currently reference the formal hearing procedures in 40 CFR 85.1807, which were originally drafted to apply to light-duty motor vehicles. After we adopted the hearing procedures in 40 CFR 85.1807, EPA's Office of Administrative Law Judges finalized a set of regulations defining formal hearing procedures that were intended to apply broadly across the agency for appeals under every applicable statute. See 40 CFR part 22, "Consolidated Rules of Practice Governing the Administrative Assessment of Civil Penalties and the Revocation/Termination or Suspension of Permits." EPA is therefore revising the regulations in 40 CFR part 1068 to simply refer to these formal hearing procedures in 40 CFR part 22.

(2) Additional Changes to General Compliance Provisions

EPA is also making numerous changes across 40 CFR part 1068 to correct errors, to add clarification, and to make adjustments based on lessons learned from implementing these regulatory provisions. This includes the following changes:

- § 1068.1: Clarify applicability of part 1068 with respect to legacy parts (such as 40 CFR parts 89 through 94).
- § 1068.20: Clarify that EPA's inspection activities do not depend on having a warrant or a court order. As noted in the standard-setting parts, EPA may deny certification or suspend or revoke certificates if a manufacturer denies EPA entry for an attempted inspection or other entry.
- § 1068.27: Clarify that EPA confirmatory testing may be performed before issuance of a certificate of conformity. We are also making an addition to state that we may require manufacturers to give us any special components that are needed for EPA testing.
- § 1068.30: Add definitions of "affiliated companies," "parent company," and "subsidiaries" to clarify

how small-business provisions apply for a range of business relationships.

- § 1068.30: Clarify that in the context of provisions that apply only for certificate holders, a manufacturer can be considered a certificate holder based on the current or previous model year (to avoid problems from having a gap between model years).

- § 1068.30: Spell out contact information for the "Designated Compliance Officer" to clarify how manufacturers should submit information to the agency. This includes email addresses for the various sectors.

- § 1068.32: Add discussion to establish the meaning of various terms and phrases for EPA regulations; for example, we distinguish between standards, requirements, allowances, prohibitions, and provisions. EPA is also clarifying terminology with respect to singular/plural, inclusive lists, notes and examples in the regulatory text, and references to "general" or "typical" circumstances. EPA also describes some of the approach to determining when "unusual circumstances" apply.

- § 1068.45: Allow manufacturers to use coded dates on engine labels; allow EPA to require the manufacturer to share information to read the coded information.

- § 1068.45: Clarify that engine labels are information submissions to EPA.

- §§ 1068.101 and 1068.125: Update penalty amounts to reflect changes to 40 CFR part 19 (81 FR 43094, July 1, 2016).

- § 1068.101: Revise the penalty associated with the tampering prohibition to be an engine-based penalty, as opposed to assessing penalties per day of engine operation. This correction aligns with Clean Air Act section 205.

- § 1068.103: Clarify the process for reinstating certificates after suspending, revoking, or voiding.

- § 1068.103: Clarify that the prohibition against "offering for sale" uncertified engines applies only for engines already produced. It is not a violation to invite customers to buy engines as part of an effort to establish the economic viability of producing engines, as would be expected for market research.

- § 1068.105: Require documentation related to "normal inventory" for stockpiling provision. EPA is also clarifying that there is no specific deadline associated with producing "normal-inventory" engines under this section, but emphasizing that vehicle/equipment manufacturers may not delay engine installation beyond their normal production schedules. EPA is also clarifying that the allowance related to building vehicles/equipment in the

early part of a model year, before the start of a new calendar year corresponding to new emission standards, applies only in cases where vehicle/equipment assembly is complete before the start of the new calendar year. This is intended to prevent manufacturers from circumventing new standards by initiating production of large numbers of vehicles/equipment for eventual completion after new standards have started to apply.

- § 1068.210: Remove the requirement for companies getting approval for a testing exemption to send us written confirmation that they meet the terms and conditions of the exemption. We do not believe this submission is necessary for implementing the testing exemption.

- § 1068.220: Add a description of how we might approve engine operation under the display exemption. This is intended to more carefully address circumstances in which engine operation is part of the display function in question. We will want to consider a wide range of factors in considering such a request; for example, we may be more inclined to approve a request for a display exemption if the extent of operation is very limited, or if the engine/equipment has emission rates that are comparable to what would apply absent the exemption. EPA is also removing the specific prohibition against generating revenue with exempted engines/equipment, since this has an unclear meaning and we can take any possible revenue generation into account in considering whether to approve the exemption on its merits.

- § 1068.230: Add a provision allowing for engine operation under the export exemption only as needed to prepare it for export (this has already been in place in part 85, and in part 1068 for engines/equipment imported for eventual export).

- § 1068.235: Clarify that the standard-setting part may set conditions on an exemption for nonroad competition engines/equipment.

- § 1068.240: Clarify that manufacturers may export engines as an alternative to being destroyed if the engine was replaced with an engine covered by the exemption provisions of § 1068.240(b).

- § 1068.240: Describe the logistics for identifying the disposition of engines being replaced under the replacement engine exemption. In particular, manufacturers will need to resolve the disposition of each engine by the due date for the report under § 1068.240(c) to avoid counting them toward the production limit for

untracked replacement engines. We are delaying the due date for the report until September 30 following the production year to allow more time for manufacturers to make these determinations.

- § 1068.240: Clarify the relationship between paragraphs (d) and (e).

- § 1068.250: Simplify the deadline for requesting small-volume hardship.

- § 1068.255: Clarify that hardship provisions for equipment manufacturers are not limited to small businesses, and that a hardship approval is generally limited to a single instance of producing exempt equipment for up to 12 months.

- § 1068.260: State that manufacturers shipping engines without certain emission-related components need to identify the unshipped components either with a performance specification (where applicable) or with specific part numbers. We are also listing exhaust piping before and after aftertreatment devices as not being emission-related components for purposes of shipping engines in a certified configuration.

- §§ 1068.260 and 1068.262: Revise the text to clarify that provisions related to partially complete engines have limited applicability in the case of equipment subject to equipment-based exhaust emission standards (such as recreational vehicles). These provisions are not intended to prevent the sale of partially complete equipment with respect to evaporative emission standards. We intend to address this in the future by changing the regulation in 40 CFR part 1060 to address this more carefully.

- § 1068.262: Revise text to align with the terminology and description adopted for similar circumstances related to shipment of incomplete heavy-duty vehicles under 40 CFR part 1037.

- § 1068.301: Revise text to more broadly describe importers' responsibility to submit information and store records and explicitly allow electronic submission of EPA declaration forms and other importation documents.

- § 1068.305: Remove the provision specifying that individuals may need to submit taxpayer identification numbers as part of a request for an exemption or exclusion for imported engines/equipment. We do not believe this information is necessary for implementing the exemption and exclusion provisions.

- § 1068.315: Allow for destroying engines/equipment instead of exporting them under the exemption for importing engines/equipment for repairs or alterations.

- § 1068.315: Remove the time constraints on approving extensions to a display exemption for imported engines/equipment. EPA will continue to expect the default time frame of one year to be appropriate, and extension of one to three years is sufficient for most cases; however, we are aware that there are occasional circumstances calling for a longer-term exemption. For example, an engine on display in a museum might appropriately be exempted indefinitely once its place in a standing exhibition is well established.

- § 1068.315: Specify that engines under the ancient engine exemption must be *substantially* in the original configuration.

- § 1068.360: Clarify the provisions related to model year for imported products by removing a circularity regarding "new" engines and "new" equipment.

- § 1068.401: Add explicit statement that SEA testing is at manufacturer's expense. This is consistent with current practice and the rest of the regulatory text.

- § 1068.401: Allow for requiring manufacturers other than the certificate holder to perform selective enforcement audits in cases where multiple manufacturers are cooperatively producing certified engines.

- § 1068.401: State that SEA non-cooperation may lead to suspended or revoked certificate (like production-line testing).

- § 1068.415: Set up new criteria for lower SEA testing rate based on engine power to allow for a reduced testing rate of one engine per day only for engines with maximum engine power above 560 kW, but keep the allowance to approve a lower testing rate; that may be needed, for example, if engine break-in (stabilization) and testing are performed on the same dynamometer. EPA believes it is more appropriate to base reduced testing rates on engine characteristics rather than sales volumes, as has been done in the past.

- § 1068.415: Revise the service accumulation requirement to specify a maximum of eight days for stabilizing a test engine. This is necessary to address a situation where an engine operates only six hours per day to achieve stabilization after well over 50 hours. For such cases, we would expect manufacturers to be able to run engines much more than six hours per day. As with testing rates, manufacturers may ask for our approval to use a longer stabilization period if circumstances don't allow them to meet the specified service accumulation targets.

- § 1068.501, and Appendix I: Clarify that "emission-related components"

include components whose failure *would commonly* increase emissions (not might increase), and whose *primary* purpose is to reduce emissions (not sole purpose); current regulations are not consistent.

- § 1068.501: Add "in-use testing" to list of things to consider for investigating potential defects.

- § 1068.505: Clarify that manufacturers subject to a mandatory recall must remedy vehicles with an identified nonconformity without regard to their age or mileage at the time of repair, consistent with provisions that already apply under 40 CFR part 85.

- § 1068.505: Revise the requirement for submitting a remedial report from a 60-day maximum to a 45-day minimum (or 30-day minimum in the event of a hearing). This adjusted approach already applies to motor vehicles under 40 CFR part 85.

- § 1068.515: Clarify an ambiguity to require that manufacturers identify the facility where repairs or inspections are performed, and allow manufacturers to keep records of those facilities rather than including the information on the recall label.

- § 1068.530: Specify that recall records must be kept for five years, rather than three years. This is consistent with longstanding recall policy for motor vehicles and motor vehicle engines under 40 CFR part 85.

In addition, EPA received a comment from Navy on behalf of the Defense Department requesting that we add a provision to allow for an automatic national security exemption in cases where a federal defense agency owns an engine that would need sulfur-sensitive technology to comply with emission standards if it is intended to be used in areas outside the United States where ultra-low sulfur fuel is unavailable. We are adopting this change as part of the final rule. This will reduce the agencies' burden to process what has become a routine process for requesting and approving these exemptions. We are also taking the opportunity to include marine diesel engines in this same section, rather than treating them separately under 40 CFR 1042.635.

We proposed to revise § 1068.201 to describe how someone may sell an engine under a different exemption than was originally intended or used as a result of unforeseen circumstances. However, we have decided to postpone those regulatory amendments to a future rule. This will give us opportunity to more thoroughly explore all relevant factors, such as:

- Statutory authority and requirements.

- Business interests for managing distribution and inventories of exempted engines.
- Environmental impacts.

E. Amendments to Light-Duty Greenhouse Gas Program Requirements

EPA is making minor changes to correct errors and clarify regulations in 40 CFR part 86, subpart S, and 40 CFR part 600 relating to EPA's light-duty fuel economy and greenhouse gas emission standards. This includes the following changes:

- § 86.1818–12: Correct a reference in paragraph (c)(4) and clarify that CO₂-equivalent debits for N₂O and CH₄ are calculated in Megagrams and rounded to the nearest whole Megagram.
- § 86.1838–01: Correct references in paragraph (d)(3)(iii).
- § 86.1866–12: Correct a reference in paragraph (b).
- § 86.1868–12: Clarify language in the introductory paragraph explaining the model years of applicability of different provisions for air conditioning efficiency credits. In paragraph (e)(5) clarify that the engine-off specification of 2 minutes is intended to be cumulative time. In paragraphs (f)(1), (g)(1), and (g)(3), clarify language by pointing to the definitions in § 86.1803–01.
- § 86.1869–12: Make corrections to the language for readability in paragraph (b)(2). In paragraph (b)(4)(ii) delete the phrase “backup/reverse lights” because these lights were not intended to be part of the stated eligibility criteria for high-efficiency lighting credits. Correct references in paragraph (f).
- § 86.1870–12: Add language that clarifies that a manufacturer that meets the minimum production volume thresholds with a combination of mild and strong hybrid electric pickup trucks is eligible for credits.
- § 86.1871–12: Clarify that credits from model years 2010–2015 are not limited to a life of 5 model years. A recent rule extended the life of 2010–2015 credits to model year 2021; thus, language referring to a 5-year life for emission credits generated in these model years is being removed or revised.
- § 600.113–12: Correct language in paragraph (m)(1), which relates to vehicles operating on LPG, that erroneously refers to methanol and methanol-fueled.
- § 600.113–12: Correct references in paragraph (n) and add a new paragraph (m) that reinstates language mistakenly dropped by a previous regulation.
- § 600.116–12: Correct description of physical quantity to refer to “energy”

rather than “current,” and correct various paragraph references.

- § 600.208–12: Correct a reference in paragraph (a)(2)(iii).
- § 600.210–12: Correct a reference and text in paragraph (c)(2)(iv)(C).
- § 600.311–12: Revise fuel economy label instructions to (1) identify label ratings for model year 2017 and earlier standards certified early to the Tier 3 standards, (2) identify label ratings for Interim Tier 3 vehicles certified to interim bins for model years 2018 through 2024, and (3) clarify that the specified California emission standards determine label ratings only if vehicles are not subject to any EPA standards. All these changes are consistent with current implementation through guidance.
- § 600.510–12: Correct a reference in the equation in paragraph (c)(1)(ii) to apply the air conditioning, off-cycle, and pickup truck credits to the appropriate fleet average MPG value. Revise the regulation to accelerate the transition to fuel economy calculations using utility factors for natural gas vehicles, consistent with the methodology that applies for plug-in hybrid vehicles. This amendment was adopted by Congress as part of Fixing America's Surface Transportation Act, H.R. 22, 114th Cong. § 24341 (2015).

F. Amendments to Highway and Nonroad Test Procedures and Certification Requirements

(1) Testing With Aftertreatment Devices Involving Infrequent Regeneration

Manufacturers generally rely on selective catalytic reaction and diesel particulate filters to meet EPA's emission standards for highway and nonroad compression-ignition engines. These emission control devices typically involve infrequent regeneration, which can have a significant effect on emission rates. EPA has addressed that for each engine type by provisions for infrequent regeneration factors; this is a calculation methodology that allows manufacturers to incorporate the effect of infrequent regeneration into reported emission values whether or not that regeneration occurs during an emission test. EPA adopted separate provisions for highway, locomotive, marine, and land-based nonroad compression-ignition engines. As proposed, EPA is harmonizing the common elements of these procedures in 40 CFR part 1065, and adding clarifying specifications in each of the standard-setting parts for sector-specific provisions. Commenters generally supported this revision. See

Section II for a discussion of how IRAFs will apply for GHGs in Phase 2.

(2) Mapping for Constant-Speed Engines Under 40 CFR Part 1065

EPA is revising 40 CFR 1065.510 as it applies to the two-point mapping method for certain constant-speed engines. The regulations previously cited a performance parameter in ISO 8528–5 that does not apply for the design of these engines.

It is common practice for engines that produce electric power to use an isochronous governor for stand-alone generator sets. In some parallel operations of multiple generator sets, droop is added as a method for load sharing. The amount of droop can be tuned by the generator set manufacturer or the site system integrator. Such engines are commonly tested on an engine dynamometer with the isochronous governor.

Mapping with just two points works well for the case of 0 percent droop (*i.e.*, isochronous governor). For this case, a persistent speed error is forced on the engine governor on the second point and this will cause the governor to wind up to its maximum command. The second point is effectively operating on the torque curve instead of the isochronous governor. So, the second point captures the full fueling torque (plus a small amount due to any rising torque curve). This measured torque is used as the maximum test torque for computing the emission test points. Since there is no designed-in droop, some target amount of speed error is needed for the second point. The regulation at 40 CFR 1065.510(d)(5)(iii) has a default target speed on the second point of 97.5 percent of the no-load speed measured on the first point. This results in a persistent speed error of 2.5 percent of the no-load speed. For an 1800 rpm no-load speed, this gives a target speed of 1755 rpm and a 45 rpm speed error on an isochronous governor. If the engine has a torque rise of 20 percent from 1800 to 1200 rpm (0.0333 percent torque rise per rpm), this 45 rpm error will cause a 1.5 percent-of-point error in the determination of the intended maximum test torque. This error is larger than desired for this type of testing. Fortunately, engines and test cells have sufficient speed resolution to select a lower speed error, which reduces this error in maximum test torque. In practice, testing with a speed error at or below 0.5 percent is more than adequate to cause the isochronous governor to wind up to maximum fueling. Using a target speed of 99.5 percent on the second point gives a target speed of 1791 rpm for an 1800

rpm no-load speed and reduces the error on the maximum test torque to a reasonable 0.3 percent of point for the 20 percent torque rise case described above.

For governors with droop, if we attempt the two-point method, we would have to calculate a target speed for the second point based on a designed amount of droop.

Unfortunately, the actual governor may not have the same amount of droop as the design droop, which may cause error in the measured torque versus the maximum test torque associated with a complete torque map. Also, the design droop may be based on a torque value that is different from the intended maximum test torque. Thus, the two-point method is not sufficient to yield a maximum test torque equivalent to the value obtained using a multi-point map. Also the allowed speed error on the second point is 20 percent of the speed droop, which allows an unacceptably large error in the maximum test torque.

Thus, for the reasons listed, we are limiting the two-point mapping method to any isochronous governed engines, not just engines used to generate electric power.

(3) Calculating Maximum and Intermediate Test Speeds Under 40 CFR Part 1065

EPA is improving the method for calculating maximum and intermediate test speeds by applying a more robust calculation method. The new calculation method is consistent with the methodology used to determine maximum test torque, which we revised in the light-duty Tier 3 rulemaking. Under the previous regulations, the result was a measured maximum test torque at one of the map points. The new calculation method involves interpolation to determine the measured maximum test torque, yielding a more representative maximum value for test torque.

(4) Excluding Ethane From Measure Emissions for Gaseous-Fueled Compression-Ignition Engines

EPA proposed to allow manufacturers to use NMOG measurements to demonstrate compliance with NMHC standards. This was primarily intended to address concerns about ethane emissions from natural gas engines inappropriately impacting compliance determinations when the engines are tested using fuels that have relatively high ethane content. Commenters shared that the proposed approach would not accomplish the intended purpose. Some commenters also emphasized that ethane is a

hydrocarbon and an organic compound that has a low ozone reactivity (*i.e.*, ethane emissions do little to contribute to ozone), and that ethane emissions are hard to remove with a catalytic converter. We are finalizing a more direct approach in which engines designed to operate on gaseous fuels are subject to hydrocarbon standards in the form of nonmethane-nonethane hydrocarbons. This approach applies for all the different sectors of mobile compression-ignition engines—heavy-duty highway, land-based nonroad, marine, and locomotive. Excluding ethane from hydrocarbon measurements requires additional test specifications as noted in the following section.

We are adopting an alternative provision that involves reduced test burden by selecting a low-ethane test fuel. In particular, EPA or manufacturers performing measurements with a test fuel containing 1.0 percent ethane or less may measure an engine's NMHC emissions and multiple this value by 0.95 to determine its nonmethane-nonethane hydrocarbon emissions, without separately measuring ethane in the exhaust.

(5) Additional Test Procedure Amendments

EPA is adopting the following additional changes to test procedures in 40 CFR part 1065 and part 1066:

- § 1065.202: Revised to prevent specific data collection errors known as aliasing. More specifically, the revision will ensure that aliasing of data collection signal due to filtering or sampling rate does not happen. We believe that all labs are currently preventing aliasing, but this should be described in the regulations.
- § 1065.266: This new section allows the use of an FTIR for determination of NMHC or NMNEHC from engines fueled solely on LPG or natural gas. The measurement of methane and ethane is also allowed for engine fueled with LPG or natural gas, in combination with a liquid fuel, for determination of NMHC or NMNEHC when subtracting methane and/or ethane from a FID-derived THC value. The intent of the NMNEHC provision is to allow the subtraction of ethane from THC in cases where the certification fuel available to the testing lab is high in ethane content.
- § 1065.275: ASTM D6348 was added as a reference method for interpretation of spectra for N₂O determination by FTIR.
- § 1065.340 and 1065.341: These sections contain a collection of editorial corrections pertaining to CVSs intended

to improve the understanding of the calibration and verification procedures.

- § 1065.366: This new section provides interference verification procedures for FTIR hydrocarbon analyzers allowed under § 1065.266.
- § 1065.640 and 1065.642: These sections contain a collection of editorial corrections pertaining to CVSs intended to improve the understanding of the calculation procedures.
- § 1065.655: Revised to separate out carbon mass fraction of fuel and fuel composition determinations into separate sections to improve readability. This section was also revised to include any fluids injected into the exhaust in the determination of the carbon mass fraction of fuel. This ensures that all fluids in the exhaust are accounted for. Provisions were also added to address how to determine properties when multiple fuel streams (*e.g.*, gaseous and liquid) are used.
- § 1065.1001: Added a definition for diesel exhaust fluid.
- § 1066.110: Revised to allow a shortening of the tailpipe for connection to the CVS and to simultaneously conduct PM background sampling with propane recovery checks. This section was also revised to change the limit on filter face velocity from 100 cm/s to 140 cm/s. The purpose of this is to increase filter mass loading. This change is based on results obtained from the CRC E-99 Phase 1 test program, which showed that there was no loss of semi-volatile PM at this higher filter face velocity. Higher filter mass loadings will help to reduce uncertainty and lessen the impact of background variability on the final PM emission value.
- § 1066.210: Revise the dynamometer force equation to incorporate grade, consistent with the coastdown procedures we are adopting for heavy-duty vehicles. For operation at a level grade, the additional parameters cancel out of the calculation.
- § 1066.605: Adding an equation to the regulations to spell out how to calculate emission rates in grams per mile. This calculation is generally assumed, but we want to include the equation to remove any uncertainty about calculating emission rates from mass emission measurements and driving distance. We also added equations to vary sample extraction ratio instead of changing flow over the filter when performing single filter per test sampling for PM measurement.
- § 1066.815: Create an exception to the maximum value for overall residence time for PM sampling methods that involve collecting samples for combined bags over a duty cycle. This is needed to accommodate the

reduced sample flow rates associated with these procedures. We also added provisions to vary sample extraction ratio instead of changing flow over the filter when performing single filter per test sampling for PM measurement.

G. Amendments Related to Locomotives in 40 CFR Part 1033

EPA's emission standards and certification requirements for locomotives and locomotive engines under the Clean Air Act are identified in 40 CFR part 1033.

EPA is revising the engine mapping provisions in 40 CFR part 1033 for locomotive testing to denote that manufacturers do not have to meet the cycle limit values in 40 CFR 1065.514 when testing complete locomotives. Also, for engine testing with a dynamometer, while the validation criteria of CFR 1065.514 apply, EPA is allowing manufacturers the option to check validation using manufacturer-declared values for maximum torque, power, and speed. This option will allow them to omit engine mapping under 40 CFR 1065.510, which is already not required. These provisions reduce test burden and cost for the manufacturer, while preserving the integrity of the certification requirements.

EPA is also adopting text that describes the alternate ramped-model cycle provisions in 40 CFR part 1033 as some of the notch setting and durations are inconsistent with the description of the duty cycle in Table 1 of 40 CFR 1033.520. EPA has determined that the table is correct as published and the error lies in the text describing how to carry out the ramped-modal test.

We are also clarifying that locomotives operating on a combination of diesel fuel and gaseous fuel are subject to NMHC standards (or NMNEHC standards), which is the same as if the locomotives operated only on gaseous fuel. With respect to in-use fuels, we are adopting a clarification in 40 CFR 1033.815 regarding allowable fuels for certain Tier 4 and later locomotives. Specifically, we note that locomotives certified on ultra-low sulfur diesel fuel, but that do not include sulfur-sensitive emission controls, may use low sulfur diesel fuel instead of ultra-low sulfur diesel fuel, consistent with good engineering judgment. For example, an obvious case where this would be appropriate (but not the only possible case), is if a railroad had emission data showing the locomotive still met the applicable standards/FELs while operating on the higher sulfur fuel.

We also requested comment on whether EPA should consider notch-specific engine/alternator efficiencies to be confidential business information. However commenters did not support making this change in the regulations.

We requested comment on extending the provisions of 40 CFR 1033.101(i) involving a less stringent CO standard in combination with a more stringent PM standard to Tier 4 locomotives. The existing provisions were developed to provide a compliance path for natural gas locomotives that reflected both the technological capabilities of natural gas locomotives and the relative environmental significance of CO and PM emissions. This provision was not applied to Tier 4 locomotives, because the applicable Tier 4 p.m. standard is already very low (0.03 g/hp-hr). Engine manufacturers commented in favor of adopting alternate standards for Tier 3 and Tier 4 locomotives. We are extending the alternate 10.0 g/bhp-hr CO standard to Tier 3 and Tier 4 locomotives; manufacturers would qualify for the less stringent CO standard by meeting a PM standard of 0.01 g/bhp-hr.

EPA is making numerous additional changes across 40 CFR part 1033 to correct errors, to add clarification, and to make adjustments based on lessons learned from implementing these regulatory provisions. This includes the following changes:

- §§ 1033.30, 1033.730, and 1033.925: Consolidate information-collection provisions into a single section.
- § 1033.101: Allow manufacturers to certify Tier 4 and later locomotives using Low Sulfur Diesel fuel instead of Ultra-Low Sulfur Diesel fuel. Manufacturers may wish to do this to show that their locomotives do not include sulfur-sensitive technology.
- § 1033.120: Reduce extended-warranty requirements to warranties that are actually provided to customers, rather than to any published warranties that are offered. The principle is that the emission-related warranty should not be less effective for emission-related items than for items that are not emission-related.
- § 1033.150: Correct the URL associated with price index information for calculating current costs.
- § 1033.201: Clarify that manufacturers may amend their application for certification after the end of the model year in certain circumstances, but they may not produce locomotives for a given model year after December 31 of the named year.
- § 1033.201: Establish that manufacturers may deliver to EPA for

testing a locomotive/engine that is identical to the test locomotive/engine used for certification. This may be necessary if the test locomotive/engine has accumulated too many hours, or if it is unavailable for any reason.

- § 1033.235: Add an explicit allowance for carryover engine families to include the same kind of within-family running changes that are currently allowed over the course of a model year. The original text may have been understood to require that such running changes be made separate from certifying the engine family for the new model year.

- §§ 1033.235, 1033.245, and 1033.601: Describe how to demonstrate compliance with dual-fuel and flexible-fuel locomotives. This generally involves testing with each separate fuel, or with a worst-case fuel blend.

- § 1033.245: Add instructions for calculating deterioration factors for sawtooth deterioration patterns, such as might be expected for periodic maintenance, such as cleaning or replacing diesel particulate filters.

- § 1033.250: Remove references to routine and standard tests, and remove the shorter recordkeeping requirement for routine data (or data from routine tests). All test records must be kept for eight years. With electronic recording of test data, there should be no advantage to keeping the shorter recordkeeping requirement for a subset of test data. EPA also notes that the eight-year period restarts with certification for a new model year if the manufacturer uses carryover data.

- § 1033.255: Clarify that rendering information false or incomplete after submitting it is the same as submitting false or incomplete information. For example, if there is a change to any corporate information or engine parameters described in the manufacturer's application for certification, the manufacturer must amend the application to include the new information.

- § 1033.255: Clarify that voiding certificates for a recordkeeping or reporting violation would be limited to certificates that relate to the particular recordkeeping or reporting failure.

- § 1033.501: Clarify how testing requirements apply differently for locomotive engines and for complete locomotives.

- § 1033.501: Add paragraph (a)(4) to remove proportionality verification for discrete-mode tests if a single batch fuel measurement is used to determine raw exhaust flow rate. This verification involves statistical assessment that is not valid for the single data point. Requiring manufacturers instead to

simply ensure constant sample flow should adequately address the concern.

- § 1033.515: Provide the option to carry out smoke testing separate from criteria pollutant measurement with a reduced time-in-notch of 3 minutes. This change reestablishes a provision that was previously allowed in 40 CFR 92.124(f).

- §§ 1033.515 and 1033.520: Update terminology by referring to “test intervals” instead of “phases.” This allows us to be consistent with terminology used in 40 CFR part 1065.

- § 1033.520: Correct the example given to describe the testing transition after the second test interval.

- §§ 1033.701 and 1033.730: Describe the process for retiring emission credits. This may be referred to as donating credits to the environment.

- § 1033.710: Clarify that it is not permissible to show a proper balance of credits for a given model by using emission credits from a future model year.

- § 1033.730: Clarify terminology for ABT reports.

- § 1033.815: Add consideration of periodic locomotive inspections in 184-day intervals.

- § 1033.901: Update the contact information for the Designated Compliance Officer.

- § 1033.915: Migrate provisions related to confidential information to 40 CFR part 1068.

We proposed to disallow amending certified configurations after the end of the model year. However, manufacturers shared in their comments that this would change the field-fix policy that has long since allowed for making such changes. We have retracted the proposed change and replaced it with a new paragraph that describes how manufacturers may amend the application for certification during and after the model year, consistent with the current policy regarding field fixes.

H. Amendments Related to Nonroad Diesel Engines in 40 CFR Part 1039

EPA is adopting two changes to 40 CFR 1039.5 to clarify the scope and applicability of standards under 40 CFR part 1039. First, EPA is stating that engines using the provisions of 40 CFR 1033.625 for non-locomotive-specific engines remain subject to certification requirements as nonroad diesel engines under 40 CFR part 1039. Such engines will need to be certified as both locomotive engines and as nonroad diesel engines. Second, EPA is revising the statement about how manufacturers may certify under 40 CFR part 1051 for engines installed in recreational vehicles (such as all-terrain vehicles or

snowmobiles). EPA is removing text that might be interpreted to mean that there are circumstances in which certification under neither part is required. The proper understanding of EPA’s policy in that regard is that certification under one part is a necessary condition for being exempted from the other part.

In 2008, EPA adopted a requirement in 40 CFR part 1042 for manufacturers to design marine diesel engines using selective catalytic reduction with basic diagnostic functions to ensure that these systems were working as intended (73 FR 37096, June 30, 2008). EPA is applying those same diagnostic control requirements to nonroad diesel engines regulated under 40 CFR part 1039. This addresses the same fundamental concern that engines will not be controlling emissions consistent with the certified configuration if the engine is lacking the appropriate quantity and quality of reductant. While some lead time is needed to make the necessary modifications, we believe it will be straightforward to apply the same designs from marine diesel engines to land-based nonroad diesel engines. EPA is accordingly requiring that manufacturers meet the new diagnostic specifications starting with model year 2018. These diagnostic controls will not affect the current policy related to adjustable parameters and inducements related to selective catalytic reduction.

EPA is making numerous changes across 40 CFR part 1039 to correct errors, to add clarification, and to make adjustments based on lessons learned from implementing these regulatory provisions. This includes the following changes:

- § 1039.2: Add a clarifying note to say that something other than a conventional “manufacturer” may need to certify engines that become new after being placed into service (such as engines converted from highway or stationary use). This is intended to address a possible assumption that only conventional manufacturers can certify engines.

- §§ 1039.30, 1039.730, and 1039.825: Consolidate information-collection provisions into a single section.

- § 1039.107: Remove the reference to deterioration factors for evaporative emissions, since there are no deterioration factors for demonstrating compliance with evaporative emission standards.

- § 1039.104(g): Correct the specified FEL cap for an example scenario illustrating how alternate FEL caps work.

- § 1039.120: Reduce extended-warranty requirements to warranties that are actually provided to the

consumer, rather than to any published warranties that are offered. The principle is that the emission-related warranty should not be less effective for emission-related items than for items that are not emission-related.

- § 1039.125: Add crankcase vent filters to the list of maintenance items.

- § 1039.125: Allow for special maintenance procedures that address low-use engines. For example, owners of recreational marine vessels may need to perform engine maintenance after a smaller number of hours than would otherwise apply based on the limited engine operation over time.

- § 1039.125: Establish a minimum maintenance interval of 1500 hours for DEF filters. This reflects the technical capabilities for filter durability and the expected maintenance in the field.

- § 1039.125: Add fuel-water separator cartridges as an example of a maintenance item that is not emission-related.

- § 1039.125: Add a clearer cross reference to clarify that particulate traps are subject to the same maintenance intervals that apply for catalysts, consistent with the originally adopted maintenance provisions for the Tier 4 standards.

- § 1039.135: Allow for including optional label content only if this does not cause the manufacturer to omit other information based on limited availability of space on the label, and identify counterfeit protection as an additional item that manufacturers may include on the label. We modified the proposed amendment in response to comments to allow for including optional labeling content as long as the additional content doesn’t cause the space limitations that prevent inclusion of other optional information.

- § 1039.201: Clarify that manufacturers may amend their application for certification after the end of the model year in certain circumstances, but they may not produce engines for a given model year after December 31 of the named year.

- § 1039.201: Establish that manufacturers may deliver to EPA for testing an engine that is identical to the test engine used for certification. This may be necessary if the test engine has accumulated too many hours, or if it is unavailable for any reason.

- § 1039.205: Replace the requirement to submit data from invalid tests with a requirement to simply notify EPA in the application for certification if test was invalidated.

- § 1039.205: Add a requirement for manufacturers to include in their application for certification a description of their practice for

importing engines, if applicable. Note that where a manufacturer's engines are imported through a wide variety of means, EPA will not require this description to be comprehensive. In such cases, a short description of the predominant practices will generally be sufficient. As noted in comments from the Truck and Engine Manufacturers Association, engine manufacturers whose primary method of importing engines is by selling them to foreign-based equipment manufacturers for eventual importation into the United States may simply state that these products may be imported at the discretion of the equipment manufacturer. We are also adding a requirement for manufacturers of engines below 560 kW to name a test lab in the United States for the possibility of us requiring tests under a selective enforcement audit. We have adopted these same requirements in many of our other nonroad programs.

- § 1039.235: Add an explicit allowance for carryover engine families to include the same kind of within-family running changes that are currently allowed over the course of a model year. The original text may have been understood to require that such running changes be made separate from certifying the engine family for the new model year.

- §§ 1039.235, 1039.240, and 1039.601: Describe how to demonstrate compliance with dual-fuel and flexible-fuel engines. This generally involves testing with each separate fuel, or with a worst-case fuel blend.

- § 1039.240: Add instructions for calculating deterioration factors for sawtooth deterioration patterns, such as might be expected for periodic maintenance, such as cleaning or replacing diesel particulate filters.

- § 1039.240: Remove the instruction related to calculating NMHC emissions from measured THC results, since this is addressed in 40 CFR part 1065.

- § 1039.250: Remove references to routine and standard tests, and remove the shorter recordkeeping requirement for routine data (or data from routine tests). All test records must be kept for eight years. With electronic recording of test data, there should be no advantage to keeping the shorter recordkeeping requirement for a subset of test data. EPA also notes that the eight-year period restarts with certification for a new model year if the manufacturer uses carryover data.

- § 1039.255: Clarify that rendering information false or incomplete after submitting it is the same as submitting false or incomplete information. For example, if there is a change to any

corporate information or engine parameters described in the manufacturer's application for certification, the manufacturer must amend the application to include the new information.

- § 1039.255: Clarify that voiding certificates for a recordkeeping or reporting violation will be limited to certificates that relate to the particular recordkeeping or reporting failure.

- § 1039.505: Correct the reference to the ISO C1 duty cycle for engines below 19 kW.

- § 1039.515: Correct the citation to 40 CFR 86.1370.

- §§ 1039.605 and 1039.610: Revise the reporting requirement to require detailed information about the previous year, rather than requiring a detailed projection for the year ahead. The information required in advance will be limited to a notification of plans to use the provisions of these sections.

- § 1039.640: Migrate engine branding to § 1068.45.

- § 1039.701 1039.730: Describe the process for retiring emission credits. This may be referred to as donating credits to the environment.

- § 1039.705: Change terminology for counting engines from "point of first retail sale" to "U.S.-direction production volume." This conforms to the usual approach for calculating emission credits for nonroad engines.

- § 1039.710: Clarify that it is not permissible to show a proper balance of credits for a given model by using emission credits from a future model year.

- § 1039.730: Clarify terminology for ABT reports.

- § 1039.740: Clarify that the averaging-set provisions apply for credits generated by Tier 4 engines, not for credits generated from engines subject to earlier standards that are used with Tier 4 engines.

- § 1039.801: Update the contact information for the Designated Compliance Officer.

- § 1039.801: Revise the definition of "model year" to clarify that the calendar year relates to the time that engines are produced under a certificate of conformity.

- § 1039.815: Migrate provisions related to confidential information to 40 CFR part 1068.

We proposed to disallow amending certified configurations after the end of the model year. However, manufacturers shared in their comments that this would change the field-fix policy that has long since allowed for making such changes. We have retracted the proposed change and replaced it with a new paragraph that describes how

manufacturers may amend the application for certification during and after the model year, consistent with the current policy regarding field fixes.

We requested comment on removing regulatory provisions for Independent Commercial Importers from 40 CFR part 1039. These provisions, copied from highway regulations many years ago, generally allow for small businesses to modify small numbers of uncertified products to be in a certified configuration using alternative demonstration procedures, but they have not been used for nonroad engines for at least the last 15 years. We consider these to be obsolete. Commenters supported removal of these provisions, so we are including this change in the final rule.

I. Amendments Related to Marine Diesel Engines in 40 CFR Parts 1042 and 1043

EPA's emission standards and certification requirements for marine diesel engines under the Clean Air Act are identified in 40 CFR part 1042.

(1) Continuous NO_x Monitoring and On-Off Controls

Manufacturers may produce certain marine diesel engines with on-off features that disable NO_x controls when the ship is operating outside of a designated Emission Control Area (ECA) as long as certain conditions are met (§ 1042.115(g)). This provision, which applies to Category 3 engines meeting EPA Tier 3 standards, is intended to address the special operating conditions posed by an ECA and allows a ship that operates in and out of designated ECAs to downgrade engine NO_x emission controls while the ship is operating outside of a designated ECA. This provision also applies for Tier 4 NO_x standards for those Category 1 and Category 2 auxiliary engines on Category 3 vessels covered by § 1042.650(d); this provision does not apply to any other auxiliary engines or to any non-Category 3 propulsion engines. Engines with allowable on-off controls must be certified to meet the previous tier of NO_x standards when the advanced NO_x control strategies are disabled.

Engines with on-off NO_x controls are required to be equipped to continuously monitor NO_x concentrations in the exhaust (§ 1042.110(d)). EPA has been asked to clarify what "continuous" means in the context of this requirement. Because the purpose of this requirement is to show that the engine complies with the NO_x emission limits on a continuous basis, continuous monitoring must be frequent enough to demonstrate that the NO_x controls are

on and are properly functioning from the time the ship enters the ECA until it leaves, which, depending on the ECA and the ship's itinerary, could be a matter of hours or days. Since many manufacturers equip their emission control systems with NO_x sensors to monitor and log the performance of the combined engine and emission control system, we are clarifying that continuous monitoring means measuring NO_x emissions at least every 60 seconds. EPA is also specifying that a manufacturer may request approval of an alternative measurement period if that is necessary for sufficiently accurate measurements. With regard to the functioning of continuous NO_x monitoring, the continuous emission measurement device must be included as part of the engine system for EPA certification. Continuous NO_x monitoring must be engaged before the ship enters an ECA and continue until after it exits the ECA. Verification of operation of the system will be included in required periodic vessel surveys and certification that cover nearly all commercial U.S. vessels. Enforcement is expected to be performed on a periodic basis by appropriate authorities when a ship is in port.

It should be noted that the above provisions with respect to on-off controls and continuous emission monitoring do not apply for the 40 CFR part 1042 PM standards. Engines certified to standards under 40 CFR part 1042 must meet the PM limits at all times, except when the operator has applied for and received permission to disable Tier 4 PM controls while operating outside the United States pursuant to any of the provisions of 40 CFR 1042.650(a) through (c).

(2) Category 1 and Category 2 Auxiliary Engines on Category 3 Vessels

The regulation at 40 CFR 1042.650(d) exempts auxiliary Category 1 and Category 2 engines installed on U.S.-flag Category 3 vessels from the part 1042 standards if those auxiliary engines meet certain conditions. This provision is intended to facilitate compliance with MARPOL Annex VI by certain qualified Category 3 vessels engaged in international trade and to simplify compliance demonstrations while those vessels are operating in foreign ports and foreign waters. EPA is adopting two revisions to make clear that the engines on the Category 3 vessel must remain in compliance with Annex VI, and EPA is adding clarifying language relating to engines with a power output of 130 kW or less.

First, EPA is revising the regulations to clarify that the urea reporting

requirements in § 1042.660(b) (which requires an owner or operator of any vessel equipped with SCR to report to EPA within 30 days of any operation of such vessel without the appropriate reductant) also apply to Category 1 and Category 2 auxiliary engines on Category 3 vessels that are covered by § 1042.650(d). This will extend the urea reporting requirements to engines between 130 and 600 kW if they rely on SCR to meet the Annex VI Tier III NO_x limits. Engines covered by § 1042.650(d) are subject to emission standards and testing requirements under MARPOL Annex VI and the NO_x Technical Code.

Second, EPA is revising 40 CFR 1042.650(d) to clarify that, while these Category 1 and Category 2 auxiliary engines may be designed with on-off NO_x controls, Annex VI requires that the engines have an EIAPP certificate demonstrating compliance with the applicable NO_x standards of Annex VI. This includes certification to demonstrate compliance with IMO Tier II NO_x standards anytime the IMO Tier III NO_x configuration is disabled.

EPA has become aware that there is some uncertainty about how the scope of EPA's implementation of Annex VI through 40 CFR part 1043 relates to engines with a power output of 130 kW or less. The existing regulations at § 1043.30 state that an EIAPP certificate is required for engines with a power output above 130 kW, but the standards described in § 1043.60 might be interpreted to apply to engines of all sizes. EPA did not intend to appear to create additional requirements or authority under 40 CFR part 1043 that is not contained in Annex VI or its implementing legislation (the Act to Prevent Pollution from Ships). EPA is therefore adding clarifying language to § 1043.60, consistent with Regulation 13 of Annex VI and APPS, to indicate that the international NO_x limits do not apply to engines with a power output of 130 kW or less. Note that EPA therefore may not issue EIAPP certificates for engines with a power output of 130 kW or less even if manufacturers request it; this also means that such auxiliary engines are not eligible for an exemption under § 1042.650(d).

(3) Natural Gas Marine Engines

EPA is also expanding provisions that apply for marine engines designed to operate on both diesel fuel and natural gas. Test requirements apply separately for each "fuel type." EPA generally considers an engine with a single calibration strategy that combines an initial pilot injection of diesel fuel to burn natural gas to be a single fuel type. This applies even if the natural gas

portion must be substantially reduced or eliminated to maintain proper engine operation at light-load conditions. If the engine has a different calibration allowing it to run only on diesel fuel, or on continuous mixtures of diesel fuel and natural gas, we would consider it to be a dual-fuel engine or a flexible-fuel engine, respectively. These terms are used consistently across EPA programs for highway and nonroad applications. There is an effort underway to revise the definition of "dual-fuel" in MARPOL Annex VI, which may be different than EPA's definition. It should be noted that the 40 CFR part 1042 certification testing requirement differs from that specified in MARPOL Annex VI and the NO_x Technical Code. While the international protocol involves testing only on the engine calibration with the greatest degree of diesel fuel, EPA certification requires manufacturers to perform testing on each separate fuel type. This would involve one set of tests with natural gas (with or without a diesel pilot fuel, as appropriate), and an additional set of tests with diesel fuel alone. This has been required since we first adopted standards, and this is the same policy that applies across all our emission control programs. EPA is also including amended regulatory language to more carefully describe these testing requirements, and to specify how this applies differently for dual-fuel and flexible-fuel engines.

(4) Additional Marine Diesel Amendments

EPA is making numerous changes across 40 CFR part 1042 to correct errors, to add clarification, and to make adjustments based on lessons learned from implementing these regulatory provisions. This includes the following changes:

- § 1042.1: Correct the tabulated applicability date for engines with per-cylinder displacement between 7 and 15 liters; this should refer to engines "at or above" 7 liters, rather than "above 7 liters."
- § 1042.1: Replace an incorrect reference to 40 CFR part 89 with a reference to 40 CFR part 94 for marine engines above 37 kW.
- § 1042.2: Add a clarifying note to say that something other than a conventional "manufacturer" may need to certify engines that become new after being placed into service (such as engines converted from highway or stationary use). This is intended to address a possible assumption that only conventional manufacturers can certify engines.

- §§ 1042.30, 1042.730, and 1042.825: Consolidate information-collection provisions into a single section.

- § 1042.101: Revise the text to more carefully identify engine subcategories and better describe the transition between Tier 3 and Tier 4 standards. These changes are intended to clarify which standards apply and are not intended to change the emission standards for any particular size or type of engine.

- § 1042.101 and Appendix III: More precisely define applicability of specific NTE standards for different types of engines and pollutants; correct formulas defining NTE zones and subzones; and add clarifying information to identify subzone points that could otherwise be derived from existing formulas. None of these changes are intended to change the standards, test procedures, or other policies for implementing the NTE standards.

- § 1042.101: Clarify the FEL caps for certain engines above 3700 kW.

- § 1042.101: Add a specification to define “continuous monitor” for parameters requiring repeated discrete measurements, as described above. The rule also includes further clarification on the relationship between on-off NO_x controls and engine diagnostic systems.

- § 1042.110: Remove the requirement to notify operators regarding an unsafe operating condition, since we can more generally rely on the broader provision in § 1042.115 that prohibits manufacturers from incorporating design strategies that introduce an unreasonable safety risk during engine operation.

- § 1042.110: Clarify that using a NO_x sensor as an alternative to monitoring DEF concentration applies only if the system includes an alert to inform operators when DEF quality is inadequate. This makes explicit what we believe should have already been understood from the requirement as originally drafted.

- § 1042.120: Reduce extended-warranty requirements to warranties that are actually provided to the consumer, rather than to any published warranties that are offered. The principle is that the emission-related warranty should not be less effective for emission-related items than for items that are not emission-related.

- § 1042.125: Add crankcase vent filters to the list of maintenance items.

- § 1042.125: Allow for special maintenance procedures that address low-use engines. For example, owners of recreational marine vessels may need to perform engine maintenance after a smaller number of hours than would

otherwise apply based on the limited engine operation over time.

- § 1042.125: Establish a minimum maintenance interval of 1500 hours for DEF filters. This reflects the technical capabilities for filter durability and the expected maintenance in the field.

- § 1042.135: Clarify that ULSD labeling is required only for engines that use sulfur-sensitive technology. If an engine can meet applicable emission standards without depending on the use of ULSD, the manufacturer should not be required to state on the engine that ULSD is required.

- § 1042.135: Allow for including optional label content only if this does not cause the manufacturer to omit other information based on limited availability of space on the label. We modified the proposed amendment in response to comments to allow for including optional labeling content as long as the additional content doesn't cause the space limitations that prevent inclusion of other optional information.

- § 1042.201: Clarify that manufacturers may amend their application for certification after the end of the model year in certain circumstances, but they may not produce engines for a given model year after December 31 of the named year.

- § 1042.201: Establish that manufacturers may deliver to EPA for testing an engine that is identical to the test engine used for certification. This may be necessary if the test engine has accumulated too many hours, or if it is unavailable for any reason.

- §§ 1042.205 and 1042.840: Replace the requirement to submit data from invalid tests with a requirement to simply notify EPA in the application for certification if test was invalidated.

- § 1042.235: Add an explicit allowance for carryover engine families to include the same kind of within-family running changes that are currently allowed over the course of a model year. The original text may have been understood to require that such running changes be made separate from certifying the engine family for the new model year.

- §§ 1042.235, 1042.240, and 1042.601: Describe how to demonstrate compliance with dual-fuel and flexible-fuel engines. This generally involves testing with each separate fuel, or with a worst-case fuel blend.

- § 1042.240: Add instructions for calculating deterioration factors for sawtooth deterioration patterns, such as might be expected for periodic maintenance, such as cleaning or replacing diesel particulate filters.

- § 1042.250: Remove references to routine and standard tests, and remove

the shorter recordkeeping requirement for routine data (or data from routine tests). All test records must be kept for eight years. With electronic recording of test data, there should be no advantage to keeping the shorter recordkeeping requirement for a subset of test data. EPA also notes that the eight-year period restarts with certification for a new model year if the manufacturer uses carryover data.

- § 1042.255: Clarify that rendering information false or incomplete after submitting it is the same as submitting false or incomplete information. For example, if there is a change to any corporate information or engine parameters described in the manufacturer's application for certification, the manufacturer must amend the application to include the new information.

- § 1042.255: Clarify that voiding certificates for a recordkeeping or reporting violation will be limited to certificates that relate to the particular recordkeeping or reporting failure.

- § 1042.301: Clarify that the requirements to test production engines does not apply for engines that become new and subject to emission standards as remanufactured engines.

- § 1042.302: Clarify that manufacturers may fulfill the requirement to test each Category 3 production engine by performing the test before or after the engine is installed in the vessel. The largest Category 3 engines are assembled in the vessel, but some smaller Category 3 engines are assembled at a manufacturing facility where they can be more easily tested. Manufacturers must perform such testing on fully assembled production engines rather than relying on test results from test bed engines.

- § 1042.501: Provide instruction on how to verify proportional sampling for discrete mode testing where only one batch fuel measurement is made over the operating mode. This requires that manufacturers hold sampling constant over the sampling period. Manufacturers will verify proportionality either over a discrete mode by using average exhaust flow rate paired with each recorded sample flow rate, or over the entire duty cycle.

- § 1042.501: Remove test procedure specifications that are already covered in 40 CFR part 1065.

- § 1042.505: Correct the reference to the ISO C1 duty cycle in 40 CFR part 1039.

- § 1042.515: Remove an incorrect cite.

- §§ 1042.605 and 1042.610: Revise the reporting requirement to require detailed information about the previous

year, rather than requiring a detailed projection for the year ahead. The information required in advance will be limited to a notification of plans to use the provisions of these sections.

- § 1042.630: Clarify that dockside examinations are not inspections. Vessels subject to Coast Guard inspection are identified in 46 U.S.C. 3301.
- §§ 1042.601 and 1042.635: Migrate the national security exemption to § 1068.225, including the expanded automatic exemption related the standards that would otherwise require sulfur-sensitive technology. See Section XIII.D(2).
- § 1042.640: Migrate engine branding to § 1068.45.
- § 1042.650: Clarify that vessel operators may modify certified engines if they will be operated for an extended period outside the United States where ULSD will be unavailable. This does not preclude the possibility of vessel operators restoring engines to a certified configuration in anticipation of bringing the vessel back to the United States.
- § 1042.660: Identify the contact information for submitting reports related to operation without SCR reductant.
- § 1042.670: Specify that gas turbine engines are presumed to have an equivalent power density below 35 kW per liter of engine displacement; this is needed to identify which Tier 3 standards apply.
- § 1042.701: Clarify that emission credits generated under 40 CFR part 94 may be used for demonstrating compliance with the Tier 3 and Tier 4 standards in 40 CFR part 1042.
- §§ 1042.701 and 1042.730: Describe the process for retiring emission credits. This may be referred to as donating credits to the environment.
- § 1042.705: Change terminology for counting engines from “point of first retail sale” to “U.S.-direction production volume.” This conforms to the usual approach for calculating emission credits for nonroad engines.
- § 1042.710: Clarify that it is not permissible to show a proper balance of credits for a given model by using emission credits from a future model year.
- § 1042.730: Clarify terminology for ABT reports.
- § 1042.810: Clarify that it is only the remanufacturing standards of subpart I, not the certification standards that are the subject of the applicability determination in § 1042.810.
- § 1042.830: Add a provision to specifically allow voluntary labeling for engines that are not subject to remanufacturing standards, and to

clarify that the label is required for engines that are subject to remanufacturing standards.

- § 1042.901: Update the contact information for the Designated Compliance Officer.
- § 1042.901: Revise the definition of “model year” to correct cites and clarify that the calendar year relates to the time that engines are produced under a certificate of conformity.
- §§ 1042.901 and 1042.910: Update the reference documents for Annex VI and NO_x Technical Code to include recent changes from the International Maritime Organization.
- § 1042.915: Migrate provisions related to confidential information to 40 CFR part 1068.

We proposed to disallow amending certified configurations after the end of the model year. However, manufacturers shared in their comments that this would change the field-fix policy that has long since allowed for making such changes. We have retracted the proposed change and replaced it with a new paragraph that describes how manufacturers may amend the application for certification during and after the model year, consistent with the current policy regarding field fixes.

J. Miscellaneous EPA Amendments

EPA is clarifying that the cold NMHC standards specified in 40 CFR 86.1811–17 do not apply at high altitude. We intended in recent amendments to state that the cold CO standards apply at both low and high altitude, but inadvertently placed that statement where it also covered cold NMHC standards, which contradicts existing regulatory provisions that clearly describe the cold NMHC standards as applying only for low-altitude testing. The change simply moves the new clarifying language to apply only to cold CO standards. We are also restoring the cold NMHC standards in paragraph (g)(2), which were inadvertently removed as part of the earlier amendments.

EPA is revising the specifications for Class 2b and Class 3 vehicles certifying early to the Tier 3 exhaust emission standards under 40 CFR 86.1816–18 to clarify that carryover values apply for formaldehyde. The Preamble to the earlier final rule described these standards properly, but the regulations inadvertently pointed to the Tier 3 values for these vehicles.

EPA is making a minor correction to the In-Use Compliance Program under 40 CFR 86.1846–01. The Light-Duty Tier 3 final rule amended this section by describing how to use SFTP test results in the compliance determination in a way that inadvertently removed a

reference to *low-mileage* SFTP testing. We are restoring the removed text.

EPA is revising the instruction for creating road-load coefficients for cold temperature testing in 40 CFR 1066.710 to simply refer back to 40 CFR 1066.305 where this is described more generally. The text originally adopted in 40 CFR 1066.710 incorrectly describes the calculation for determining those coefficients.

EPA is also adopting two minor amendments related to highway motorcycles. First, we are correcting an error related to the small-volume provisions for highway motorcycles. The regulation included an inadvertent reference to a small-volume threshold based on an annual volume of 3,000 motorcycles produced in the United States. As written, this would not consider any foreign motorcycle production for importation into the United States. This error is corrected by simply revising the text to refer to an annual production volume of motorcycles produced “for” the United States. This change properly reflects small-volume production as it relates to compliance with EPA standards. Second, we are clarifying the language describing how to manage the precision of emission results, both for measured values and for calculating values when applying a deterioration factor. This involves a new reference to the rounding procedures in 40 CFR part 1065 to replace the references to outdated ASTM procedures.

K. Competition Vehicles

The proposal included a clarification related to vehicles used for competition to ensure that the Clean Air Act requirements are followed for vehicles used on public roads. This clarification is not being finalized. EPA supports motorsports and its contributions to the American economy and communities all across the country. EPA’s focus is not (nor has it ever been) on vehicles built or used exclusively for racing, but on companies that violate the rules by making and selling products that disable pollution controls on motor vehicles used on public roads. These unlawful defeat devices lead to harmful pollution and adverse health effects. The proposed language was not intended to represent a change in the law or in EPA’s policies or practices towards dedicated competition vehicles. Since our attempt to clarify led to confusion, EPA has decided to eliminate the proposed language from the final rule.

EPA will continue to engage with the racing industry and others in its support for racing, while maintaining the Agency’s focus where it has always

been: Reducing pollution from the cars and trucks that travel along America's roadways and through our neighborhoods.

L. Amending 49 CFR Parts 512 and 537 To Allow Electronic Submissions and Defining Data Formats for Light-Duty Vehicle Corporate Average Fuel Economy (CAFE) Reports

To improve efficiency and reduce the burden to manufacturers and the agencies, NHTSA proposed to amend 49 CFR part 537 to eliminate the option for manufacturers to submit pre-model, mid-model and supplemental reports on CD-ROMS, and require only one electronic submission (for each report) electronically via a method proscribed by NHTSA. NHTSA planned to introduce a new electronic format to standardize the method for collecting manufacturer's information. NHTSA also proposed modifying 49 CFR part 512 to include and protect submitted CAFE data elements that need to be treated as confidential business information. For the final rule, NHTSA is not finalizing this proposal in this rulemaking but will consider electronic submission for CAFE reports in a future action.

XIV. Statutory and Executive Order Reviews

A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

This action is an economically significant regulatory action that was submitted to the Office of Management and Budget (OMB) for review. Any changes made in response to OMB recommendations have been documented in the docket. The agencies prepared an analysis of the potential costs and benefits associated with this action. This analysis, the "Regulatory Impact Analysis—Heavy-Duty GHG and Fuel Efficiency Standards," is available in the docket. The analyses contained in this document are also summarized in Sections VII, VIII, and IX of this Preamble.

B. National Environmental Policy Act

This section describes NHTSA's Environmental Impact Statement (EIS) process under the National Environmental Policy Act (NEPA), 42 U.S.C. 4321–4347, and implementing regulations issued by the Council on Environmental Quality (CEQ), 40 CFR parts 1500–1508, and NHTSA, 49 CFR part 520. Pursuant to 49 U.S.C. 304a(b) and DOT's "Final Guidance on MAP–21 Section 1319 Accelerated Decision

making in Environmental Reviews,"⁹⁹² NHTSA is issuing a Final Environmental Impact Statement (FEIS)⁹⁹³ concurrently with its final rule. This Preamble constitutes the Record of Decision (ROD) for NHTSA's final rule establishing Phase 2 fuel efficiency standards for heavy-duty engines and vehicles.⁹⁹⁴ NHTSA has determined that concurrent issuance of the FEIS and ROD is not precluded by statutory criteria⁹⁹⁵ or practicability considerations.

The first subsection below describes the agency's NEPA process to date, including its scoping notice and Draft Environmental Impact Statement (DEIS). The second subsection describes the FEIS, and the third subsection discusses the ROD. The final subsection includes other regulatory notices related to environmental concerns.

(1) Scoping Notice and Draft Environmental Impact Statement

Under NEPA, a Federal agency must prepare an EIS on proposals for major Federal actions that significantly affect the quality of the human environment.⁹⁹⁶ The purpose of an EIS is to inform decision makers and the public of the potential environmental impacts of a proposed action and reasonable alternative actions the agency could take.⁹⁹⁷ The EIS is used by the agency, in conjunction with other

relevant material, to plan actions and make decisions.

On July 9, 2014, NHTSA published a notice of intent to prepare an EIS for this rulemaking and requested scoping comments (79 FR 38842). The notice invited Federal, State, and local agencies, Indian tribes, stakeholders, and the public to participate in the scoping process and to help identify the environmental issues and reasonable alternatives to be examined in the EIS. NHTSA considered the comments received on that notice as it prepared its DEIS.

NHTSA released a DEIS for this rulemaking on June 19, 2015, concurrently with its release of the NPRM.⁹⁹⁸ NHTSA prepared the DEIS to analyze and disclose the potential environmental impacts of the HD fuel consumption standards and a reasonable range of alternatives. Environmental impacts analyzed in the DEIS included those related to fuel and energy use, air quality, and climate change. The DEIS also described potential environmental impacts to a variety of resource areas, including water resources, biological resources, land use and development, safety, hazardous materials and regulated wastes, noise, socioeconomic, and environmental justice. These resource areas were assessed qualitatively in the DEIS.

The DEIS analyzed five alternative approaches to regulating HD vehicle fuel consumption, including a "preferred alternative" and a "no action alternative." The DEIS evaluated a reasonable range of alternatives under NEPA, and analyzed the direct, indirect, and cumulative impacts of those alternatives in proportion to their significance.

Because of the link between the transportation sector and GHG emissions, NHTSA recognizes the need to consider the possible impacts on climate and global climate change in the analysis of the effects of its fuel consumption standards. NHTSA also recognizes the difficulties and uncertainties involved in such an impact analysis. Accordingly, consistent with CEQ regulations on addressing incomplete or unavailable information in environmental impact analyses, NHTSA reviewed existing credible scientific evidence that was relevant to this analysis and summarized it in the DEIS. NHTSA also employed and summarized the results of research

⁹⁹² Section 1319(b) ("Accelerated Decision making in Environmental Reviews") of the Moving Ahead for Progress in the 21st Century Act (MAP–21), Public Law 112–141, instructed a lead agency on an EIS, "to the maximum extent practicable," to develop a "single document that consists of a final environmental impact statement and a record of decision." DOT implemented this provision through guidance, clarifying that "[i]n the case of a NEPA review for a rulemaking where the final rule is the Record of Decision, the [DOT operating administration] should make the completed FEIS available to the decision maker simultaneously with the final rule, unless it is determined that statutory criteria or practicability considerations preclude issuance of the combined document." See https://www.transportation.gov/sites/dot.gov/files/docs/MAP-21_1319_Final_Guidance.pdf. Section 1319 was subsequently repealed by Section 1304(j)(2) of the Fixing America's Surface Transportation Act (FAST Act), Public Law 114–94. However, in the same Act, Congress codified an identical provision at 49 U.S.C. 304a. FAST Act, Sec. 1311(a). Because the provision requiring, "to the maximum extent practicable . . . a single document" was not otherwise amended, the requirement and DOT's implementation remain unchanged.

⁹⁹³ The agency's FEIS is available at its Fuel Economy Web site (<http://www.nhtsa.gov/fuel-economy/>), as well as in Docket No. NHTSA–2014–0074 on [Regulations.gov](http://www.regulations.gov) (<http://www.regulations.gov>).

⁹⁹⁴ See 40 CFR 1505.2.

⁹⁹⁵ 49 U.S.C. 304a(b)(1)–(2).

⁹⁹⁶ 40 CFR 1502.3.

⁹⁹⁷ 40 CFR 1502.1.

⁹⁹⁸ The agency's DEIS is available at its Fuel Economy Web site (<http://www.nhtsa.gov/fuel-economy/>), as well as in Docket No. NHTSA–2014–0074 on [Regulations.gov](http://www.regulations.gov) (<http://www.regulations.gov>).

models generally accepted in the scientific community.

Although the alternatives have the potential to decrease GHG emissions substantially, the DEIS found they do not prevent climate change, but only result in reductions in the anticipated increases in CO₂ concentrations, temperature, precipitation, and sea level. They will also, to a small degree, delay the point at which certain temperature increases and other physical effects stemming from increased GHG emissions will occur. As discussed in the DEIS, NHTSA presumes that these reductions in climate effects will be reflected in reduced impacts on affected resources. The EPA and the U.S. Department of Energy served as cooperating agencies in the preparation of the DEIS. The DEIS informed NHTSA decision makers in their preparation of the NPRM and in the ongoing rulemaking process. In the DEIS and NPRM, NHTSA invited comments on the DEIS from Federal, State, and local agencies, Indian tribes, stakeholders, and the public by August 31, 2015. NHTSA mailed (both electronically and through U.S. mail) notification of its availability to individuals and entities identified in Chapter 10 of the DEIS. In addition, EPA published a Notice of Availability of the DEIS on June 26, 2015, officially triggering the public comment period.⁹⁹⁹ NHTSA subsequently extended the comment period to October 1, 2015.¹⁰⁰⁰ Comments on the EIS were also invited at the joint NHTSA/EPA public hearings held on the NPRM.

(2) Final Environmental Impact Statement

NHTSA received many written and oral comments to the NPRM and the DEIS. The written comments submitted to NHTSA and the transcripts from the public hearings are part of the administrative record and are available on the Federal Docket, available online at <http://www.regulations.gov/>, Reference Docket Nos. NHTSA–2014–0074 and NHTSA–2014–0132. NHTSA reviewed, analyzed, and considered all relevant comments it received during the public comment period. The agency then updated and revised the DEIS to prepare the FEIS, which is being released concurrently with this final rule and ROD. For a more detailed discussion of the comments NHTSA received, including the agency's responses to those comments, see Chapter 9 of the FEIS.

In developing the Phase 2 fuel efficiency standards for heavy-duty engines and vehicles adopted in this final rule, NHTSA has been informed by the analyses contained in the *Final Environmental Impact Statement, Phase 2 Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles*, Docket No. NHTSA–2014–0074.

NHTSA will submit the FEIS to EPA, in accordance with CEQ NEPA implementing regulations and EPA guidance.¹⁰⁰¹ Prior to submission, NHTSA will post the FEIS on its Web site and in the public docket, as well as notify stakeholders and interested parties identified in Chapter 11 of the FEIS about its availability (both electronically and through U.S. mail). EPA will then publish a Notice of Availability of the FEIS in the **Federal Register**.

(3) Record of Decision

For Federal actions requiring an EIS, the CEQ regulations instruct the action agency to prepare a concise public “record of decision” at the time of its decision. The ROD must state: (1) The agency's decision; (2) all alternatives considered by the agency in reaching its decision, specifying the alternative or alternatives that were considered to be environmentally preferable; (3) the agency's preferences among alternatives based on relevant factors, including economic and technical considerations and agency statutory missions; (4) the factors balanced by the agency in making its decision, including any essential considerations of national policy; (5) how these factors and considerations entered into the agency's decision; and (6) whether all practicable means to avoid or minimize environmental harm from the alternative selected have been adopted, and if not, why they were not.¹⁰⁰² As stated above, this Preamble constitutes the ROD for NHTSA's final rule establishing Phase 2 fuel efficiency standards for heavy-duty engines and vehicles.

(a) The Agency's Decision

In the DEIS and FEIS, NHTSA identified Alternative 3 as the Preferred Alternative. Alternative 3, as analyzed in the FEIS, is the regulation finalized by NHTSA in this rulemaking. The standards would result in significant improvements in fuel efficiency for heavy-duty engines and vehicles. These final standards are included at the end

of this document, described extensively in this Preamble, and analyzed for economic and environmental impacts in the RIA and FEIS.

In sum, after carefully reviewing and analyzing all of the information in the public record, RIA, FEIS, and public and agency comments submitted on the DEIS and NPRM, NHTSA has decided to finalize the Preferred Alternative.

(b) Alternatives NHTSA Considered in Reaching Its Decision

When preparing an EIS, NEPA requires an agency to compare the potential environmental impacts of its proposed action and a reasonable range of alternatives. In the DEIS and FEIS, NHTSA analyzed a No Action Alternative and four action alternatives, which represent a range of potential actions the agency could take. The environmental impacts of these alternatives, in turn, represent a range of potential environmental impacts that could result from NHTSA's chosen action in setting fuel efficiency standards for heavy-duty engines and vehicles.

The No Action Alternative in the DEIS and FEIS assumes that NHTSA would not issue a final rule regarding Phase 2 fuel efficiency standards for heavy-duty engines and vehicles. Instead, it assumes that NHTSA's Phase 1 standards would continue indefinitely. The No Action Alternative therefore reflects the average fuel efficiency levels and GHG emissions performance that manufacturers would achieve without additional regulation. This alternative provided an analytical baseline against which to compare the environmental impacts of the other alternatives presented in the EIS. NEPA expressly requires agencies to consider a “no action” alternative in their NEPA analyses and to compare the effects of not taking action with the effects of action alternatives in order to demonstrate the environmental effects of the action alternatives.¹⁰⁰³

In the DEIS, in addition to the No Action Alternative, NHTSA analyzed a reasonable range of action alternatives with fuel efficiency standards at various

¹⁰⁰³ See 40 CFR 1502.2(e), 1502.14(d). CEQ has explained that “[T]he regulations require the analysis of the no action alternative even if the agency is under a court order or legislative command to act. This analysis provides a benchmark, enabling decision makers to compare the magnitude of environmental effects of the action alternatives. [See 40 CFR 1502.14(c).] * * * Inclusion of such an analysis in the EIS is necessary to inform Congress, the public, and the President as intended by NEPA. [See 40 CFR 1500.1(a).]” Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, 46 FR 18026 (Mar. 23, 1981).

¹⁰⁰¹ See CEQ implementing regulations at 40 CFR 1506.9; EPA EIS filing guidance at 77 FR 51530 (Aug. 24, 2012).

¹⁰⁰² 40 CFR 1505.2.

⁹⁹⁹ 80 FR 36803 (Jun. 26, 2015).

¹⁰⁰⁰ 80 FR 53513 (Sep. 4, 2015).

levels of stringency, with Alternative 2 the least stringent and Alternative 5 the most stringent. The exact levels of stringency for each alternative were described in Chapter 2 of the DEIS. As noted in the DEIS, based on the different ways the agency could weigh the various considerations, NHTSA believed that the “maximum feasible improvement” in heavy-duty vehicle and engine fuel efficiency fell within that range. In the FEIS, the levels of stringency for Alternatives 2, 4, and 5 are unchanged from the DEIS and are described in Chapter 2 of the FEIS.¹⁰⁰⁴ However, Alternative 3 (the Preferred Alternative) was revised in response to public comments and additional research. The changes to Alternative 3 are explained extensively in this Preamble, and are reflected in the FEIS.¹⁰⁰⁵

Alternatives 2 and 5 were intended to provide the lower and upper bounds of a reasonable range of alternatives. In the EIS, the agency provided environmental analyses of these points, as well as intermediate points, to enable decision makers and the public to determine the environmental impacts of other points that fall between Alternatives 2 and 5. The action alternatives evaluated in the EIS therefore provided decision makers with the ability to select from a wide variety of other potential alternatives with stringencies that fall between Alternatives 2 and 5.

According to the FEIS, Alternative 5 is the overall Environmentally Preferable Alternative because it would result in the largest overall reductions in fuel use and emissions of criteria air pollutants, toxic air pollutants, and GHGs among the alternatives considered.¹⁰⁰⁶ Under each action

alternative the agency considered, the reduction in fuel consumption resulting from greater fuel efficiency causes reductions in GHG emissions compared to the No Action Alternative. In addition, as fuel consumption declines, emissions that occur during fuel refining and distribution also decline. While there may be some increases in fuel consumption and associated tailpipe and upstream emissions resulting from increased driving due to the fuel efficiency rebound effect, these increases are more than offset by reductions resulting from the improved fuel efficiency of regulated heavy vehicles, leading to a net reduction in total emissions. The criteria air pollutant, toxic air pollutant, and GHG emissions reductions are anticipated to improve overall health outcomes and reduce the impacts of climate change on the human environment. As Alternative 5 would result in the greatest reductions in fuel consumption, it also results in the lowest total air pollutant and GHG emissions, and is therefore Environmentally Preferable.¹⁰⁰⁷

The environmental impacts associated with the alternatives under consideration are described in Chapters 3–7 of the FEIS. NHTSA considered these environmental impacts in making its decision, and incorporates that analysis by reference here.

(c) NHTSA’s Preferences Among Alternatives Based on Relevant Factors; Factors Balanced by NHTSA in Making Its Decision; and How These Factors and Considerations Entered Into NHTSA’s Decision

NHTSA considered various relevant factors in setting Phase 2 fuel efficiency standards for heavy-duty engines and vehicles, including economic, technical, and environmental considerations, as well as safety considerations, consistent with the agency’s statutory mission. This Preamble, which constitutes the ROD for NHTSA’s final rule, provides a complete discussion of the agency’s preferences among alternatives based on relevant factors, the factors balanced by the agency in making its decision, and how the factors and considerations balanced by the agency entered into its decision.

(d) Mitigation

The CEQ regulations specify that a ROD must “state whether all practicable means to avoid or minimize environmental harm from the alternative selected have been adopted, and if not, why they were not.”¹⁰⁰⁸ In essence, this regulation requires NHTSA to address mitigation in the ROD.¹⁰⁰⁹ The overwhelming majority of the environmental effects of NHTSA’s action are positive (*i.e.*, beneficial environmental impacts) and would not raise issues of mitigation. Overall emissions of criteria and toxic air pollutants are generally projected to decrease under the final standards as compared to their levels under the No Action Alternative. However, analysis of the environmental trends reported in the FEIS for the Preferred Alternative indicates small emissions increases for some air pollutants in some near-term analysis years. The agency forecasts emissions increases for some alternatives because, under all the alternatives analyzed in the FEIS, increases in vehicle use due to improved fuel efficiency are projected to result in growth in total miles traveled by heavy-duty vehicles. The growth in VMT outpaces emissions reductions for some pollutants, resulting in projected increases for these pollutants. In addition, NHTSA’s NEPA analysis predicted increases in emissions of some air pollutants under certain alternatives based on assumptions about the type of technologies manufacturers will use to comply with the standards (particularly APU use). However, for the reasons described in Section 5.5.2.3 of the RIA, some of those air pollutant increases are no longer anticipated to occur.

Although limited harmful impacts of the final standards are projected in some near-term analysis years in the FEIS, the overall environmental impacts of the final standards are anticipated to be overwhelmingly beneficial. NHTSA’s authority to promulgate new fuel efficiency standards for heavy-duty vehicles and engines does not allow the agency to regulate criteria or toxic air pollutants from vehicles or factors affecting those emissions, such as driving habits. Consequently, NHTSA must set fuel efficiency standards but is unable to take steps to mitigate the limited harmful impacts of those standards. However, EPA has taken additional action in this final rule to control PM emissions resulting from APU use that, for the reasons described

¹⁰⁰⁴ The environmental impacts reported for these alternatives in the FEIS differ from those reported in the DEIS. These differences result from minor changes in modeling assumptions (such as VMT, fleet profile, upstream emission levels, etc.), technology penetration and effectiveness assumptions, and other incremental updates resulting from public comments and additional research.

¹⁰⁰⁵ As a result of these changes, Alternative 3 is more stringent than Alternative 4 in some heavy-duty segments, and more stringent overall. NHTSA did not renumber the alternatives (to maintain increasing stringency from Alternative 2 to Alternative 5) in order to allow readers to more easily compare the DEIS to the FEIS, as well as to maintain Alternatives 2, 4, and 5 as benchmarks to which the Preferred Alternative may be compared.

¹⁰⁰⁶ Although NHTSA is required to identify the Environmentally Preferable Alternative under the CEQ regulations (40 CFR 1505.2(b)), it is under no obligation to select that alternative in its decision. This ROD explains the agency’s preferences among alternatives, the factors balanced by the agency in making its decision (including environmental considerations), and how the factors and considerations balanced by the agency entered into its decision.

¹⁰⁰⁷ For some toxic air pollutants, Alternative 3 is the Environmentally Preferable Alternative because it results in the greatest reductions of emissions of those pollutants. However, the greater overall stringency of Alternative 5 results in greater overall emissions reductions among criteria and toxic air pollutants. As a consequence, Alternative 5 results in the greatest reductions of adverse health effects resulting from heavy duty vehicle emissions.

¹⁰⁰⁸ 40 CFR 1505.2(c).

¹⁰⁰⁹ 40 CFR 1508.20.

in Section 5.5.2.3 of the RIA, would mitigate some of the projected harmful impacts. Further, Chapter 8 of the FEIS outlines a number of other initiatives across the government that could ameliorate the environmental impacts of motor vehicle use, including the use of heavy-duty vehicles.

(4) Other Regulatory Notices Related to Environmental Concerns

This section includes regulatory determinations related to environmental concerns that are not otherwise included in the FEIS. For example, NHTSA addresses the following in the FEIS: Conformity requirements under the Clean Air Act (Chapter 4.1.1.4), the National Historic Preservation Act (Chapter 7.2), and Environmental Justice (Chapter 7.5).

(a) Coastal Zone Management Act (CZMA)

The Coastal Zone Management Act¹⁰¹⁰ provides for the preservation, protection, development, and (where possible) restoration and enhancement of the nation's coastal zone resources. Under the statute, States are provided with funds and technical assistance in developing coastal zone management programs. Each participating State must submit its program to the Secretary of Commerce for approval. Once the program has been approved, any activity of a Federal agency, either within or outside of the coastal zone, that affects any land or water use or natural resource of the coastal zone must be carried out in a manner that is consistent, to the maximum extent practicable, with the enforceable policies of the State's program.

NHTSA concludes that the CZMA is not applicable to the agency's decision because it does not involve any activity within, or outside of, the nation's coastal zones as intended by the statute. These standards would mitigate some of the anticipated impacts of global climate change, including potential impacts to coastal zones that would otherwise have occurred in the absence of agency action. However, the agency's action will not directly affect any land or water use or natural resource of a coastal zone.

The agency has conducted a qualitative review of the related direct, indirect, and cumulative impacts of the alternatives on potentially affected resources, including coastal zones, in the FEIS. See Chapter 5.5 of the FEIS.

(b) Floodplain Management (Executive Orders 11988 and 13690; DOT Order 5650.2)

These Orders require Federal agencies to avoid the long- and short-term adverse impacts associated with the occupancy and modification of floodplains, and to restore and preserve the natural and beneficial values served by floodplains. Executive Order 11988 also directs agencies to minimize the impact of floods on human safety, health, and welfare, and to restore and preserve the natural and beneficial values served by floodplains through evaluating the potential effects of any actions the agency may take in a floodplain and ensuring that its program planning and budget requests reflect consideration of flood hazards and floodplain management. DOT Order 5650.2 sets forth DOT policies and procedures for implementing Executive Order 11988. The DOT Order requires that the agency determine if a proposed action is within the limits of a base floodplain, meaning it is encroaching on the floodplain, and whether this encroachment is significant. If significant, the agency is required to conduct further analysis of the proposed action and any practicable alternatives. If a practicable alternative avoids floodplain encroachment, then the agency is required to implement it.

In this rulemaking, the agency is not occupying, modifying, or encroaching on floodplains. The agency, therefore, concludes that the Orders are not applicable to NHTSA's decision. The agency has, however, conducted a review of the alternatives on potentially affected resources, including floodplains, in the FEIS. See Chapter 5.5 of the FEIS.

(c) Preservation of the Nation's Wetlands (Executive Order 11990 & DOT Order 5660.1A)

These Orders require Federal agencies to avoid, to the extent possible, undertaking or providing assistance for new construction located in wetlands unless the agency head finds that there is no practicable alternative to such construction and that the proposed action includes all practicable measures to minimize harms to wetlands that may result from such use. Executive Order 11990 also directs agencies to take action to minimize the destruction, loss, or degradation of wetlands in "conducting Federal activities and programs affecting land use, including but not limited to water and related land resources planning, regulating, and licensing activities." DOT Order 5660.1A sets forth DOT policy for

interpreting Executive Order 11990 and requires that transportation projects "located in or having an impact on wetlands" should be conducted to assure protection of the Nation's wetlands. If a project does have a significant impact on wetlands, an EIS must be prepared.

The agency is not undertaking or providing assistance for new construction located in wetlands. In addition, the agency's action will not affect land use in wetlands, nor is it a transportation project "located in or having an impact on wetlands." Therefore, the agency concludes that these Orders do not apply to NHTSA's decision. The agency has, however, conducted a review of the alternatives on potentially affected resources, including wetlands. See Section 5.5 of the FEIS.

(d) Department of Transportation Act (Section 4(f))

Section 4(f) of the Department of Transportation Act of 1966 (49 U.S.C. 303), as amended, is designed to preserve publicly owned parklands, waterfowl and wildlife refuges, and significant historic sites. Specifically, Section 4(f) provides that DOT agencies cannot approve a transportation program or project that requires the use of any publicly owned land from a significant public park, recreation area, or wildlife and waterfowl refuge, or any land from a significant historic site, and results in a greater than *de minimis* impact unless a determination is made that:

- There is no feasible and prudent alternative that completely avoids the use of Section 4(f) property, and
- The program or project includes all possible planning to minimize harm to the Section 4(f) property resulting from the transportation use.

This rulemaking is not a transportation program or project that requires the use of any publicly owned land. As a result, NHTSA concludes that Section 4(f) is not applicable to NHTSA's decision.

C. Paperwork Reduction Act

The information collection activities in these final rules will be submitted for approval to the Office of Management and Budget (OMB) under the PRA. The Information Collection Request (ICR) document that EPA prepared has been assigned EPA ICR number 2394.05 and OMB Control Number 2060-0678. You can find a copy of the ICR in the docket for these final rules, and it is briefly summarized here. The burden estimates in this section account for the collective information collection burden imposed

¹⁰¹⁰ 16 U.S.C. 1451–1466 (as amended).

by both agencies. The information collection requirements are not enforceable until OMB approves them.

The agencies will collect information to ensure compliance with the provisions in these rules. This includes a variety of testing, reporting and recordkeeping requirements for vehicle and engine manufacturers. Section 208(a) of the CAA requires that manufacturers provide information the Administrator may reasonably require to determine compliance with the regulations; submission of the information is therefore mandatory. We will consider confidential all information meeting the requirements of section 208(c) of the CAA.

Respondents/affected entities:

Respondents are manufacturers of engines and vehicles within the North American Industry Classification System (NAICS) and use the coding structure as defined by NAICS. 336111, 336112, 333618, 336120, 541514, 811112, 811198, 336111, 336112, 422720, 454312, 541514, 541690, 811198, 333618, 336510, for Motor Vehicle Manufacturers, Engine and Truck Manufacturers, Truck Trailer Manufacturers, Commercial Importers of Vehicles and Vehicle Components, and Alternative Fuel Vehicle Converters and Manufacturers.

Respondent's obligation to respond:

The information that is subject to this collection is collected whenever a manufacturer applies for a certificate of conformity. Under section 206 of the CAA (42 U.S.C. 7521), a manufacturer must have a certificate of conformity before a vehicle or engine can be introduced into commerce.

Estimated number of respondents: It is estimated that this collection affects approximately 141 engine and vehicle manufacturers.

Frequency of response: Annually.

Total estimated burden: The burden to the manufacturers affected by these rules has a range based on the number of engines and vehicles a manufacturer produces. The estimated average annual respondent burden associated with the first three implementation years of the Phase 2 program is 61,800 hours (see Table XIV-1). This estimated burden for engine and vehicle manufacturers is an average estimate for both new and existing reporting requirements for calendar years 2017, 2018 and 2019, in which trailer manufacturers will prepare for and begin certifying for Phase 2 while Phase 1 will continue for the other affected manufacturers. Burden is defined at 5 CFR 1320.3(b). Burden means the total time, effort, or financial resources expended by persons to generate, maintain, retain, or disclose

or provide information to or for a Federal agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information, processing and maintaining information, and disclosing and providing information; adjust the existing ways to comply with any previously applicable instructions and requirements; train personnel to be able to respond to a collection of information; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information.

TABLE XIV-1—BURDEN FOR REPORTING AND RECORDKEEPING REQUIREMENTS

Number of Affected Engine and Vehicle Manufacturers.	141.
Annual Labor Hours for Each Manufacturer to Prepare and Submit Required Information.	Varies.
Total Annual Information Collection Burden.	61,800 Hours.

Total estimated cost: The estimated average annual cost associated with the first three implementation years of the Phase 2 program is approximately \$8 million. This includes approximately \$3 million in capital and operation & maintenance costs. This estimated cost for engine and vehicle manufacturers is an average estimate for both new and existing testing, recordkeeping, and reporting requirements for calendar years 2017, 2018 and 2019, in which trailer manufacturers will prepare for and begin certifying for Phase 2 while Phase 1 will continue for the other affected manufacturers.

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations in title 40 are listed in 40 CFR part 9. When OMB approves this ICR, the Agency will announce that approval in the **Federal Register** and publish a technical amendment to 40 CFR part 9 to display the OMB control number for the approved information collection activities contained in this final rule.

D. Regulatory Flexibility Act

I certify that this action will not have a significant economic impact on a substantial number of small entities under the RFA. The small entities subject to the requirements of this

action are small businesses. EPA has determined that less than 20 percent, and fewer than 100 regulated entities in each sector may experience an impact of greater than one percent of their annual revenue. Details of this analysis are presented in Chapter 12 of the Regulatory Impact Analysis located in the rulemaking docket (EPA-HQ-OAR-2014-0827), and are summarized below.

Pursuant to section 603 of the RFA, the agencies prepared an initial regulatory flexibility analysis (IRFA) for the proposed rule. Pursuant to section 609(b) of the RFA, the EPA convened a Small Business Advocacy Review (SBAR) Panel to obtain advice and recommendations from representatives of small entities that would potentially be regulated by the rule. A summary of the IRFA and the SBAR Panel's recommendations is presented in the proposed rule (at 80 FR 40542, July 13, 2015). The Final Panel Report is also available in the rulemaking docket.

The agencies identified four industries that would be potentially affected by this rulemaking: Alternative fuel engine converters, heavy-duty engine manufacturers, vocational vehicle chassis manufacturers, and trailer manufacturers. The agencies proposed and sought comment on the recommendations from the Panel. The flexibilities proposed for the engine manufacturers, engine converters, vocational vehicle manufacturers, and glider manufacturers are adopted in the final rule and fewer than 20 percent of the small entities in those sectors are estimated to incur a burden greater than one percent of their annual revenue. In addition to the flexibilities proposed for the trailer program, the agencies reduced the number of small entities regulated by the final rules by limiting the non-box trailer program to three distinct trailer types. As a result, 73 small business trailer manufacturers have zero burden from this rulemaking. Of the remaining small business trailer manufacturers, only 12 percent are estimated to have an economic impact greater than one percent of their annual revenue. As a result of these findings, EPA believes it can certify that these rules will not have a significant economic impact on a substantial number of small entities under the RFA. See Chapter 12.7 and 12.8 of the Regulatory Impact Analysis (RIA) of these rules for a more detailed description of the flexibilities adopted for and economic effects on the small businesses in these sectors.

(1) Legal Basis for Agency Action

Heavy-duty vehicles are classified as those with gross vehicle weight ratings

(GVWR) of greater than 8,500 lb. section 202(a) of the Clean Air Act (CAA) allows EPA to regulate new vehicles and new engines by prescribing emission standards for pollutants which the Administrator finds “may reasonably be anticipated to endanger public health or welfare.” In 2009, EPA found that six greenhouse gases (GHGs) were anticipated to endanger public health or welfare, and new motor vehicles and new motor vehicle engines contribute to

that pollution. This finding was upheld by the unanimous court in *Coalition for Responsible Regulation v. EPA*, 684 F.3d 102 (D.C. Cir. 2012). Acting under the authority of the CAA, EPA set the first phase of heavy-duty vehicle GHG standards (Phase 1) and specified certification requirements for emissions of four GHGs emitted by mobile sources: carbon dioxide (CO₂), nitrous oxide (N₂O), methane (CH₄), and hydrofluorocarbons (HFC).

(2) Summary of Potentially Affected Small Entities

Table XIV–2 provides an overview of the primary SBA small business categories potentially affected by this regulation. EPA is not aware of any small businesses that manufacture complete heavy-duty pickup trucks and vans or Class 7 and 8 tractors.

TABLE XIV–2—PRIMARY SMALL BUSINESS CATEGORIES POTENTIALLY AFFECTED BY THIS REGULATION

Industry expected in rulemaking	Industry NAICS ^a code	NAICS description	Defined as small entity by SBA if less than or equal to:
Alternative Fuel Engine Converters	333999 811198	Misc. General Purpose Machinery All Other Automotive Repair & Maintenance.	500 employees. \$7.5 million (annual receipts).
Voc. Vehicle Chassis, Class 7 & 8 Tractor Manufacturers.	336120	Heavy-Duty Truck Manufacturing ..	1,500 employees.
HD Trailer Manufacturers	336212	Truck Trailer Manufacturing	1,000 employees.
HD Engine Manufacturers	336310	Motor Vehicle Gasoline Engine & Engine Parts.	1,000 employees.

Note:

^a North American Industrial Classification System.

EPA used the criteria for small entities developed by the Small Business Administration under the North American Industry Classification System (NAICS) as a guide. Information about these entities comes from sources including EPA’s certification data, trade association databases, and previous rulemakings that have affected these industries. EPA then found employment information for these companies using the business information database Hoover’s Online (a subsidiary of Dan and Bradstreet). These entities fall under the categories listed in the table.

The agencies believe there are about 178 trailer manufacturers and 147 of these manufacturers qualify as small entities with 1,000 employees or less.¹⁰¹¹ EPA and NHTSA identified ten heavy-duty engine manufacturers that are currently certifying natural gas engines. Six of these companies are small businesses. Seventeen companies meet EPA requirements under 40 CFR part 85 as alternative fuel engine converters. We believe all 17 of the engine converters qualify as small businesses. Currently, 20 manufacturers that make chassis for vocational vehicles certify with EPA under the Phase 1 program and the agencies have identified an additional 19 small

vocational chassis manufacturers that are not currently certifying under Phase 1.

Glider kits and glider vehicles are a subset of tractor and vocational vehicles under the final Phase 2 rulemaking (including for regulation of criteria pollution emissions). Glider vehicle manufacturers traditionally purchase or manufacture new vehicle bodies (vocational vehicles or Class 7 and 8 tractors) for use with older powertrains and/or complete assembly of these vehicles by installing the powertrain. The agencies were aware of four glider vehicle manufacturers (for whom glider vehicle production was a primary business) at the time of the SBAR Panel and we identified three of these manufacturers as small entities. We are not aware of any small businesses that produce glider kits for others to assemble.¹⁰¹² Public comments to the proposed rule indicated that nearly 1,200 purchasers of glider kits, and we presume they would all meet the Act’s definition of “manufacturer”, which includes anyone who assembles motor vehicles. See Section I.E.(1)(c). We believe a majority of these manufacturers qualify as small businesses. However, it is likely that few of these entities that purchase glider kits do so as their primary business. It is likely that many (if not most) of these

entities assemble gliders for their own use from glider kits produced by large heavy-duty vehicle manufacturers. NHTSA is not finalizing fuel efficiency regulations applicable to gliders or glider kits at this time.

(3) Potential Reporting, Recordkeeping and Compliance Burdens

For any emission control program, EPA must have assurances that the regulated products will meet the standards. The program that EPA is adopting for manufacturers subject to this rule will include testing, reporting, and recordkeeping requirements. Testing requirements for these manufacturers include use of EPA’s Greenhouse gas Emissions Model (GEM) vehicle simulation tool to obtain the overall CO₂ emissions rate for certification of vocational chassis and trailers, aerodynamic testing to obtain aerodynamic inputs to GEM for some tractor and trailer manufacturers and engine dynamometer testing for alternative fuel engine converters to ensure their conversions meet the CO₂, CH₄ and N₂O engine standards. Reporting requirements will likely include emissions test data or model inputs and results, technical data related to the vehicles, and end-of-year sales information. Manufacturers will have to keep records of this information.

(4) Related Federal Rules

The primary federal rule that is related to the Phase 2 rules under consideration is the 2011 Greenhouse

¹⁰¹¹ The Small Business Administration amended its classification criteria for trailer manufacturers between the NPRM and this final rule. The threshold for qualifying as a small business trailer manufacturer is now 1,000 employees. Previously the small business threshold for trailer manufacturers was 500 employees.

¹⁰¹² Although this discussion is written based on the assumption that no small businesses produce glider kits for others to assemble, the conclusions would also be valid with respect to small entities that produce glider kits for sale, should they exist.

Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles (76 FR 57106, September 15, 2011). The Phase 1 program will continue to be in effect in the absence of these final rules. Small businesses are exempt under the Phase 1 program. California adopted its own greenhouse gas initiative, which places aerodynamic requirements on trailers used in long-haul applications.

(5) Summary of SBREFA Panel Process and Panel Outreach

(a) Significant Panel Findings

The Small Business Advocacy Review Panel (SBAR Panel, or the Panel) considered regulatory options and flexibilities to help mitigate potential adverse effects on small businesses as a result of these rules. During the SBREFA Panel process, the Panel sought out and received comments on the regulatory options and flexibilities that were presented to SERs and Panel members. The recommendations of the Panel are described below and are also located in the SBREFA Final Panel Report, which is available in the public docket.

(b) Panel Process

As required by section 609(b) of the RFA, as amended by SBREFA, we also conducted outreach to small entities and convened an SBAR Panel to obtain advice and recommendations of representatives of the small entities that potentially will be subject to the rule's requirements. On October 22, 2014, EPA's Small Business Advocacy Chairperson convened a Panel under section 609(b) of the RFA. In addition to the Chair, the Panel consisted of the Division Director of the Assessment and Standards Division of EPA's Office of Transportation and Air Quality, the Chief Counsel for Advocacy of the Small Business Administration, and the Administrator of the Office of Information and Regulatory Affairs within the Office of Management and Budget.

As part of the SBAR Panel process, we conducted outreach with representatives of small businesses that will potentially be affected by the final rulemaking. We met with these Small Entity Representatives (SERs) to discuss the potential rulemaking approaches and potential options to decrease the impact of the rulemaking on their industries. We distributed outreach materials to the SERs; these materials included background on the rulemaking, possible regulatory approaches, and possible rulemaking alternatives. The Panel met with SERs from the industries that will be directly

affected by the Phase 2 rules on November 5, 2014 (trailer manufacturers) and November 6, 2014 (engine converters and vocational vehicle chassis manufacturers) to discuss the outreach materials and receive feedback on the approaches and alternatives detailed in the outreach packet. The Panel also met with SERs on July 19, 2014 for an initial, introductory outreach meeting, and held a supplementary outreach meeting with the trailer manufacturer SERs on October 28, 2014. The Panel received written comments from the SERs following each meeting in response to discussions had at the meeting and the questions posed to the SERs by the agency. The SERs were specifically asked to provide comment on regulatory alternatives that could help to minimize the rule's impact on small businesses.

The Panel's findings and discussions were based on the information that was available during the Panel process and issues that were raised by the SERs during the outreach meetings and in their comments. It was agreed that EPA should consider the issues raised by the SERs and discussions had by the Panel itself, and that EPA should consider comments on flexibility alternatives that would help to mitigate negative impacts on small businesses to the extent legally allowable by the Clean Air Act.

Alternatives discussed throughout the Panel process included those offered in previous or current EPA rulemakings, as well as alternatives suggested by SERs and Panel members. A summary of these recommendations is detailed below, and a full discussion of the regulatory alternatives and hardship provisions discussed and recommended by the Panel can be found in the SBREFA Final Panel Report. A complete discussion of the provisions for which we are requesting comment and/or proposing in this action can be found in Sections IV.E and V.D of this Preamble with a summary in Chapter 12 of the RIA. Also, the Panel Report includes all comments received from SERs (Appendix B of the Report) and summaries of the two outreach meetings that were held with the SERs. In accordance with the RFA/SBREFA requirements, the Panel evaluated the aforementioned materials and SER comments on issues related to the IRFA. The Panel's recommendations from the Final Panel Report are discussed below.

(c) Panel Recommendations

(i) Small Business Trailer Manufacturers

Comments from trailer manufacturer SERs indicated that these companies are familiar with most of the technologies

presented during our outreach, but have no experience with EPA certification and do not anticipate they could manage the accounting and reporting requirements without additional staff and extensive training. Performance testing, which is a common requirement for many of EPA's regulatory programs, is largely unfamiliar to these small business manufacturers and the SERs believed the cost of testing would be a significant burden on their companies. In light of this feedback, the Panel recommended a combination of streamlined compliance and targeted exemptions for these small businesses based on the specific trailer types that they manufacture. The Panel believed these strategies would achieve many of the benefits for the environment by driving adoption of CO₂-reducing technologies, while significantly reducing the burden that these new regulations would introduce on small businesses.

(ii) Box Trailer Manufacturers

Box trailer manufacturers have the benefit of relying on the aerodynamic technology development initiated through EPA's voluntary SmartWay program. The Panel was aware that EPA planned to propose a simplified compliance program for all manufacturers, in which aerodynamic device manufacturers have the opportunity to test and certify their devices with EPA as technologies that can be used by trailer manufacturers in their trailer certification. This pre-approved technology strategy was intended to provide all trailer manufacturers a means of complying with the standards without the burden of testing. In the event that this strategy is limited to the early years of the trailer program for all manufacturers, the Panel recommended that small manufacturers continue to be given the option to use pre-approved devices in lieu of testing.

In the event that small trailer manufacturers adopt pre-approved aerodynamic technologies and the appropriate tire technologies for compliance, the Panel recommended an alternative compliance pathway in which small business trailer manufacturers could simply report to EPA that all of their trailers include approved technologies in lieu of collecting all of the required inputs for the GEM vehicle simulation.

(iii) Non-Box Trailer Manufacturers

The Panel recommended no aerodynamic requirements for non-box trailers. The non-box trailer SERs indicated that they had no experience installing aerodynamic devices and had

only seen them in prototype-level demonstrations. In terms of the aerodynamic devices currently in use, most non-box trailer SERs identified unique operations in which their trailers are used that preclude the use of those technologies.

Some non-box trailer manufacturers had experience with LRR tires and ATI systems. However, the non-box trailer manufacturer SERs indicated that LRR tires are not currently available for some of their trailer types. The SERs noted that tire manufacturers are currently focused on box trailer applications and there are only a few LRR tire models that meet the needs of their customers. The Panel recommended EPA ensure appropriate availability of these tires in order for it to be deemed a feasible means of achieving these standards and recommended a streamlined compliance process based on the availability of technologies. The Panel suggested the best compliance option from a small business perspective would be for EPA to pre-approve tires, similar to the approach being proposed for aerodynamic technologies, and to maintain a list that could be used to exempt small businesses when no suitable tires are available. However, the Panel recognized the difficulties of maintaining an up-to-date list of certified technologies. The Panel recommended that, if EPA did not adopt the list-based approach, the agency consider a simplified letter-based compliance option that allows manufacturers to petition EPA for an exemption if they are unable to identify tires that meet the LRR performance requirements on a trailer family basis.

(iv) Non-Highway Trailer Manufacturers

The Panel recommended excluding all trailers that spend a significant amount of time in off-road applications. These trailers may not spend much time at highway speeds and aerodynamic devices may interfere with the vehicle's intended purpose. Additionally, tires with lower rolling resistance may not provide the type of traction needed in off-road applications.

(v) Compliance Provisions for all Small Trailer Manufacturers

Due to the potential for reducing a small business's competitiveness compared to the larger manufacturers, as well as the ABT recordkeeping burden, the Panel recommended that EPA consider small business flexibilities to allow small entities to opt out of ABT without placing themselves at a competitive disadvantage to larger firms that adopt ABT, such as a low volume exemption or requiring only

LRR where appropriate. EPA was asked to consider flexibilities for small businesses that would ease and incentivize their participation in ABT, such as streamlined the tracking requirements for small businesses. In addition, the Panel recommended that EPA request comment on the feasibility and consequences of ABT for the trailer program and additional flexibilities that will promote small business participation.

(vi) Lead Time Provisions for all Small Trailer Manufacturers

For all trailer types that will be included in the rule, the Panel recommended a 1-year delay in implementation for small trailer manufacturers at the start of the program to allow them additional lead time to make the proper staffing adjustments and process changes and possibly add new infrastructure to meet these requirements. In the event that EPA is unable to provide pre-approved technologies for manufacturers to choose for compliance, the Panel recommended that EPA provide small business trailer manufacturers an additional 1-year delay for each subsequent increase in stringency. This additional lead time will allow these small businesses to research and market the technologies required by the new standards.

(vii) Small Business Alternative Fuel Engine Converters

To reduce the compliance burden of small business engine converters who convert engines in previously-certified complete vehicles, the Panel recommended allowing engine compliance to be sufficient for certification—meaning that the converted vehicle would not need to be recertified *as a vehicle*. This recommended flexibility would eliminate the need for these small manufacturers to gather all of the additional component-level information in addition to the engine CO₂ performance necessary to properly certify a vehicle with GEM (e.g., transmission data, aerodynamic performance, tire rolling resistance, etc.). In addition, the Panel recommended that small engine converters be able to submit an engineering analysis, in lieu of measurement, to show that their converted engines do not increase N₂O emissions. Many of the small engine converters are converting SI-engines, and the catalysts in these engines are not expected to substantially impact N₂O production. Small engine converters that convert CI-engines could

likely certify by ensuring that their controls require changes to the SCR dosing strategies.

The Panel did not recommend separate standards for small business natural gas engine manufacturers. The Panel stated that it believes this would discourage entrance for small manufacturers into this emerging market by adding unnecessary costs to a technology that has the potential to reduce CO₂ tailpipe emissions. In addition, the Panel noted that additional leakage requirements beyond a sealed crankcase for small business natural gas-fueled CI engines and requirements to follow industry standards for leakage could be waived for small businesses with minimal impact on overall GHG emissions.

Finally, the Panel recommended that small engine converters receive a one-year delay in implementation for each increase in stringency throughout the program. This flexibility will provide small converters additional lead time to obtain the necessary equipment and perform calibration testing if needed.

(viii) Emergency Vehicle Chassis Manufacturers

Fire trucks, and many other emergency vehicles, are built for high level of performance and reliability in severe-duty applications. Some of the CO₂-reducing technologies listed in the materials could compromise the fire truck's ability to perform its duties and many of the other technologies simply provide no benefit in real-world emergency applications. The Panel recommended proposing less stringent standards for emergency vehicle chassis manufactured by small businesses. The Panel suggested that feasible standards could include adoption of LRR tires at the baseline Phase 2 level and installation of a Phase 2-compliant engine. In addition, the Panel recommended a simplified certification approach for small manufacturers who make chassis for emergency vehicles that reduces the number of inputs these manufacturers must obtain for GEM.

(ix) Off-Road Vocational Vehicle Chassis Manufacturers

At the time of the Panel process, EPA's intent was to continue the exemptions in Phase 1 for off-road and low-speed vocational vehicles (see generally 76 FR 57175). These provisions currently apply for vehicles that are defined as "motor vehicles" per 40 CFR 85.1703, but may conduct most of their operations off-road. Vehicles qualifying under these provisions must comply with the applicable engine standard, but need not comply with a

vehicle-level GHG standard. The Panel concluded this exemption is sufficient to cover the small business chassis manufacturers who design chassis for off-road vocational vehicles.

(x) Custom Chassis Manufacturers

The Panel concluded that chassis designed for specialty operations often have limited ability to adopt CO₂ and fuel consumption-reducing technologies due to their unique use patterns. In addition, the manufacturers of these chassis have very small annual sales volumes. The Panel recommended that EPA propose a low volume exemption for these custom chassis manufacturers. The Panel did not receive sufficient information to recommend a specific sales volume, but recommended that EPA request comment on how to design a small business exemption by means of a volume exemption, and an appropriate annual sales volume threshold.

(xi) Glider Manufacturers

The Panel was aware that EPA would like to reduce the production of glider vehicles that have higher emissions of criteria pollutants like NO_x and PM than current engines, and which could have higher GHG emissions than Phase 2 engines. However, the Panel estimated that the number of vehicles produced by the small businesses who manufacture glider kits is too small to have a substantial impact on the total heavy-duty GHG inventory and recommended that existing small businesses be allowed to continue assembling glider vehicles without having to comply with the GHG requirements.¹⁰¹³ The Panel recommended that EPA establish an allowance for existing small business glider manufacturers to produce some number of glider vehicles for legitimate purposes, such as for newer vehicles badly damaged in crashes. The Panel recommended that any other limitations on small business glider production be flexible enough to allow sales levels as high as the peak levels in the 2010–2012 timeframe.

E. Unfunded Mandates Reform Act

This action contains a federal mandate under UMRA, 2 U.S.C. 1531–1538, that may result in expenditures of \$100 million or more for state, local and tribal governments, in the aggregate, or the private sector in any one year. Accordingly, the agencies have prepared a statement required under section 202 of UMRA. The statement is included in

the docket for this action and briefly summarized here.

The agencies have prepared a statement of the cost-benefit analysis as required by section 202 of the UMRA; this discussion can be found in this Preamble, and in the RIA. The agencies believe that this action represents the least costly, most cost-effective approach to achieve the statutory requirements of the rules. Section IX explains why the agencies believe that the fuel savings that will result from this action will lead to lower prices economy wide, improving U.S. international competitiveness. The costs and benefits associated with this action are discussed in more detail above in Section IX and in the Regulatory Impact Analysis, as required by the UMRA.

This action is not subject to the requirements of section 203 of UMRA because it contains no regulatory requirements that might significantly or uniquely affect small governments.

F. Executive Order 13132: Federalism

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government.

In the spirit of Executive Order 13132, and consistent with EPA policy to promote communications between EPA and State and local governments, EPA specifically solicited comment from State and local officials on the proposed rules.

NHTSA notes that EPCA contains a provision (49 U.S.C. 32919(a)) that expressly preempts any State or local government from adopting or enforcing a law or regulation related to fuel economy standards or average fuel economy standards for automobiles covered by an average fuel economy standard under 49 U.S.C. Chapter 329. However, commercial medium- and heavy-duty on-highway vehicles and work trucks are not “automobiles,” as defined in 49 U.S.C. 32901(a)(3). In Phase 1 NHTSA concluded that EPCA’s express preemption provision will not reach the fuel efficiency standards to be established in this rulemaking. NHTSA is reiterating that conclusion here for the Phase 2 standards.

NHTSA also considered the issue of implied or conflict preemption. The possibility of such preemption is dependent upon there being an actual conflict between a standard established by NHTSA in this rulemaking and a State or local law or regulation. See *Spiestma v. Mercury Marine*, 537 U.S.

51, 64–65 (2002). At present, NHTSA has no knowledge of any State or local law or regulation that will actually conflict with one of the fuel efficiency standards to be established in this rulemaking.

G. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

This action does not have tribal implications as specified in Executive Order 13175. These rules will be implemented at the Federal level and impose compliance costs only on vehicle and engine manufacturers. Tribal governments will be affected only to the extent they purchase and use regulated vehicles. Thus, Executive Order 13175 does not apply to this action.

Although Executive Order 13175 does not apply to this action, EPA and NHTSA specifically solicited additional comment from tribal officials in developing this action.

H. Executive Order 13045: Protection of Children From Environmental Health Risks and Safety Risks

This action is subject to Executive Order 13045 because it is an economically significant regulatory action as defined by Executive Order 12866, and the agencies believe that the environmental health or safety risk addressed by this action may have a disproportionate effect on children. Accordingly, we have evaluated the environmental health or safety effects of these risks on children. The results of this evaluation are discussed below.

A synthesis of the science and research regarding how climate change may affect children and other vulnerable subpopulations is contained in the Technical Support Document for Endangerment or Cause or Contribute Findings for Greenhouse Gases under section 202(a) of the Clean Air Act, which can be found in the public docket for this action. In making those findings, EPA Administrator placed weight on the fact that certain groups, including children, are particularly vulnerable to climate-related health effects. In those findings, EPA Administrator also determined that the health effects of climate change linked to observed and projected elevated concentrations of GHGs include the increased likelihood of more frequent and intense heat waves, increases in ozone concentrations over broad areas of the country, an increase of the severity of extreme weather events such as hurricanes and floods, and increasing severity of coastal storms due to rising sea levels. These effects can all increase

¹⁰¹³ The Panel was unaware of the enormous increase in glider vehicle production in recent years, and its attendant adverse environmental impacts. See section XIII.B.(3) and (4) and RTC Section 14.2.

mortality and morbidity, especially in vulnerable populations such as children, the elderly, and the poor. In addition, the occurrence of wildfires in North America have increased and are likely to intensify in a warmer future. PM emissions from these wildfires can contribute to acute and chronic illnesses of the respiratory system, including pneumonia, upper respiratory diseases, asthma, and chronic obstructive pulmonary disease, especially in children.

The agencies have estimated reductions in projected global mean surface temperature and sea level rise as a result of reductions in GHG emissions associated with the standards finalized in this action (Section VII and NHTSA's FEIS). Due to their vulnerability, children may receive disproportionate benefits from these reductions in temperature and the subsequent reduction of increased ozone and severity of weather events.

Children are also more susceptible than adults to many air pollutants because of differences in physiology, higher per body weight breathing rates and consumption, rapid development of the brain and bodily systems, and behaviors that increase chances for exposure. Even before birth, the developing fetus may be exposed to air pollutants through the mother that affect development and permanently harm the individual.

Infants and children breathe at much higher rates per body weight than adults, with infants under one year of age having a breathing rate up to five times that of adults.¹⁰¹⁴ In addition, children breathe through their mouths more than adults and their nasal passages are less effective at removing pollutants, which leads to a higher deposition fraction in their lungs.¹⁰¹⁵

Certain motor vehicle emissions present greater risks to children as well. Early life stages (e.g., children) are thought to be more susceptible to tumor development than adults when exposed to carcinogenic chemicals that act through a mutagenic mode of action.¹⁰¹⁶

Exposure at a young age to these carcinogens could lead to a higher risk of developing cancer later in life.

The adverse effects of individual air pollutants may be more severe for children, particularly the youngest age groups, than adults. The Integrated Science Assessments and Criteria Documents for a number of pollutants affected by these rules, including those for NO₂, SO₂, PM, ozone and CO, describe children as a group with greater susceptibility. Section VIII.A.8 discusses a number of childhood health outcomes associated with proximity to roadways, including evidence for exacerbation of asthma symptoms and suggestive evidence for new onset asthma. In general, these studies do not identify the specific contaminants associated with adverse effects, instead addressing the near-roadway environment as one containing numerous exposures potentially associated with adverse health effects.

There is substantial evidence that people who live or attend school near major roadways are more likely to be of a minority race, Hispanic ethnicity, and/or low SES. Within these highly exposed groups, children's exposure and susceptibility to health effects is greater than adults due to school-related and seasonal activities, behavior, and physiological factors.

Section VIII.C and NHTSA's FEIS describe the expected emissions reductions for non-GHG co-pollutants resulting from these standards. These emissions reductions will lead to reductions in ambient concentrations of PM_{2.5}, ozone and other non-GHG co-pollutants. Children are not expected to experience greater ambient concentrations of air pollutants than the general population. However, because of their greater susceptibility to air pollution and their increased time spent outdoors, it is likely that these standards will have particular benefits for children's health.

I. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use

This action is not a "significant energy action" because it is not likely to have a significant adverse effect on the supply, distribution or use of energy. In fact, these rules have a positive effect on energy supply and use. Because the combination of the fuel economy standards and the GHG emission standards will result in significant fuel savings, this action encourages more

efficient use of fuels. Therefore, we have concluded that this action is not likely to have any adverse energy effects. Our energy effects analysis is described above in Section IX and NHTSA's FEIS.

J. National Technology Transfer and Advancement Act and 1 CFR Part 51

This action involves technical standards.

The agencies are using the following voluntary consensus standards from SAE International:

- SAE J1025 (August 2012) is a voluntary consensus standard describing how to determine a tire's characteristic value for revolutions per mile. This replaces the proposed approach in which we instructed manufacturers to determine and use tire diameter as an input for modeling vehicle emissions.
- SAE J1252 (July 2012) is a voluntary consensus standards that describes aerodynamic measurement procedures for wind tunnels. Heavy-duty vehicle testing already relies on these reference standards under 40 CFR part 1066.
- SAE J1263 (March 2010) and SAE J2263 (December 2008) are voluntary consensus standards that together establish a test protocol to determine road-load coefficients for properly testing vehicles on a chassis dynamometer to simulate in-use operating conditions. Heavy-duty vehicle testing already relies on these reference standards under 40 CFR part 1066.
- SAE J1594 (July 2010) is a voluntary consensus standards that describes vehicle aerodynamics terminology. Heavy-duty vehicle testing already relies on these reference standards under 40 CFR part 1066.
- SAE J1930 (October 2008) is a voluntary consensus standards that describes terms and abbreviations for engine and vehicle technologies. We are adopting an updated standard to reflect the current version.
- SAE J2071 (Revised June 1994) is a voluntary consensus standards that describes specifications for wind tunnels.
- SAE J2343 (July 2008). This voluntary consensus standard establishes a minimum hold time for LNG-fueled vehicles following a refueling event before the tank vents to relieve pressure. This is described further in Section XIII.A.3.
- SAE J2452 (June 1999) is a voluntary consensus standards that describes a procedure for measuring tire rolling resistance as part of a coastdown procedure.
- SAE J2966 (September 2013) is a voluntary consensus standards that

¹⁰¹⁴ U.S. Environmental Protection Agency. (2009). Metabolically-derived ventilation rates: a revised approach based upon oxygen consumption rates. Washington, DC: Office of Research and Development. EPA/600/R-06/129F. <http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=202543>.

¹⁰¹⁵ Foos, B.; Marty, M.; Schwartz, J.; Bennet, W.; Moya, J.; Jarabek, A.M.; Salmon, A.G. (2008) Focusing on children's inhalation dosimetry and health effects for risk assessment: an introduction. J Toxicol Environ Health 71A: 149–165.

¹⁰¹⁶ U.S. Environmental Protection Agency. (2005). Supplemental guidance for assessing susceptibility from early-life exposure to carcinogens. Washington, DC: Risk Assessment Forum. EPA/630/R-03/003F. http://www3.epa.gov/raff/publications/pdfs/childrens_supplement_final.pdf.

describes a protocol for using computational fluid dynamics to determine aerodynamic drag.

The regulations for the Phase 1 standards included a reference to SAE J1526 as a test procedure for measuring in-use fuel consumption. An updated version of SAE J1526 was adopted in September 2015. As noted in the proposed rule, we are revising the regulations to reference the updated version of SAE J1526. All SAE documents are available from the publisher's Web site at www.sae.org.

We are adopting a standard to facilitate measurement with fourier transform infrared (FTIR) analyzers—ASTM D6348 (February 2012). We are also adopting an updated version of ASTM D4809–13, which specifies test methods for determining the heat of combustion of liquid hydrocarbon fuels for both Phase 1 and Phase 2 standards.

We are referencing a new supplement to ANSI NGV1, which we already use for defining system requirements for compressed natural gas vehicles. The supplement from the same publisher is known as CSA IR–1–15, “Compressed Natural Gas Vehicle (NGV) High Flow Fueling Connection Devices.” This document is available from the ANSI Web site at www.ansi.org. The supplement will eventually be incorporated into ANSI NGV1, at which point we would no longer need to reference to CSA IR–1–15.

This action also involves technical standards for which there is no available voluntary consensus standard. First, the agencies are adopting greenhouse gas emission standards for heavy-duty vehicles that depend on computer modeling to predict an emission rate based on various engine and vehicle characteristics. Such a model is not available from other sources, so EPA has developed the Greenhouse Gas Emission Model as a simulation tool for demonstrating compliance with emission standards. See Section II for a detailed description of the model. A working version of this software is available for download at <http://www3.epa.gov/otaq/climate/gem.htm>.

Second, 40 CFR part 1037 includes several test procedures involving calculation with numerous physical quantities. We are incorporating by reference NIST Special Publication 811 to allow for standardization and consistency of units and nomenclature. This standard, which already applies for 40 CFR parts 1065 and 1066, is published by the National Institute of Standards and Technology (Department of Commerce) and is available at no charge at www.nist.gov.

Third, the amendments for marine diesel engines involve technical standards related to the requirements that apply internationally. There are no voluntary consensus documents that address these technical standards. In earlier rulemakings, EPA has adopted an incorporation by reference for MARPOL Annex VI and the NO_x Technical code in 40 CFR parts 1042 and 1043. The International Maritime Organization adopted changes to these documents in 2013 and 2014, which need to be reflected in 40 CFR parts 1042 and 1043. EPA recently adopted the updated reference documents in 40 CFR part 1043. As noted in Section XIV.H.4, this rule includes the remaining step of incorporating the updated IMO documents by reference in 40 CFR part 1042. All these documents are available at www.imo.org.

K. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

The agencies believe the human health or environmental risk addressed by this action will not have potential disproportionately high and adverse human health or environmental effects on minority, low-income or indigenous populations. The results of this evaluation are discussed below.

With respect to GHG emissions, the agencies have determined that these final rules will not have disproportionately high and adverse human health or environmental effects on minority, low-income or indigenous populations because they increase the level of environmental protection for all affected populations without having any disproportionately high and adverse human health or environmental effects on any population, including any minority, low-income or indigenous population. The reductions in CO₂ and other GHGs associated with the standards will affect climate change projections, and the agencies have estimated reductions in projected global mean surface temperatures (Section VII and NHTSA's FEIS). Within communities experiencing adverse impacts related to climate change, certain parts of the population may be especially vulnerable; these include the poor, the elderly, those already in poor health, the disabled, those living alone, and/or indigenous populations dependent on one or a few resources.¹⁰¹⁷

¹⁰¹⁷ EPA 2009. Technical Support Document for Endangerment and Cause of Contribute Findings for Greenhouse Gases under section 202(a) of the Clean Air Act. Available at: <http://www3.epa.gov/climatechange/Downloads/endangerment/>

For non-GHG co-pollutants such as ozone, PM_{2.5}, and toxics, the agencies have concluded that it is not practicable to determine whether there will be disproportionately high and adverse human health or environmental effects on minority, low income and/or indigenous populations from these rules. As discussed in Section VIII and NHTSA's FEIS, however, based on the magnitude of the non-GHG co-pollutant emissions changes predicted to result from these standards, EPA and NHTSA expect that there will be improvements in ambient air quality that will likely help in mitigating the disparity in racial, ethnic, and economically-based exposures.

L. Endangered Species Act (ESA)

Section 7(a)(2) of the ESA requires federal agencies, in consultation with the National Oceanic and Atmospheric Administration Fisheries Service and/or the U.S. Fish and Wildlife Service (FWS), to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of federally listed endangered or threatened species or result in the destruction or adverse modification of designated critical habitat of such species. 16 U.S.C. 1536(a)(2). Under relevant implementing regulations, section 7(a)(2) applies only to actions where there is discretionary federal involvement or control. 50 CFR 402.03. Further, consultation is required only for actions that “may affect” listed species or critical habitat. 50 CFR 402.14. Consultation is not required where the action has no effect on such species or habitat. Under this standard, it is the federal agency taking the action that evaluates the action and determines whether consultation is required. See 51 FR 19926, 19949 (June 3, 1986). Effects of an action include both the direct and indirect effects that will be added to the environmental baseline. 50 CFR 402.02. Indirect effects are those that are caused by the action, later in time, and that are reasonably certain to occur. *Id.* To trigger a consultation requirement, there must be a causal connection between the federal action, the effect in question, and the listed species, and the effect must be reasonably certain to occur.

As discussed in this Preamble and the FEIS, the agencies note that the projected environmental effects of this rule are highly positive. However, the fact that the rule will have overall positive effects on the environment does not mean that the rule “may affect” any listed species or designated critical

[climatechange/Downloads/endangerment/Endangerment_TSD.pdf](http://www3.epa.gov/climatechange/Downloads/endangerment/Endangerment_TSD.pdf).

habitat within the meaning of ESA section 7(a)(2) or the implementing regulations or require ESA consultation. We have carefully considered various types of potential environmental effects, including emissions of GHGs and non-GHGs, in reaching the conclusion that ESA consultation is not required for this rule.

With respect to the projected GHG emission reductions, we are mindful of significant legal and technical analysis undertaken by FWS and the U.S. Department of the Interior in the context of listing the polar bear as a threatened species under the ESA. In that context, in 2008, FWS and DOI expressed the view that the best scientific data available were insufficient to draw a causal connection between GHG emissions and effects on the species in its habitat.¹⁰¹⁸ The DOI Solicitor concluded that where the effect at issue is climate change, actions involving GHG emissions cannot pass the “may affect” test of the section 7 regulations and thus are not subject to ESA consultation. Similarly, for this action, in the absence of a causal connection between the final rules and an effect to listed species or critical habitat that is reasonably certain to occur, no consultation is required.

The agencies have also previously considered issues relating to GHG emissions in connection with the requirements of ESA section 7(a)(2). Although the GHG emission reductions projected for this rule are large, EPA evaluated comparable or larger reductions in assessing this same issue in the context of the light duty vehicle GHG emission standards for model years 2012–2016 and 2017–2025. There the agency projected emission reductions comparable to, or greater than those projected here over the lifetimes of the model years in question and, based on air quality modeling of potential environmental effects, concluded that “EPA knows of no modeling tool which can link these small, time-attenuated changes in global metrics to particular effects on listed species in particular areas. Extrapolating from global metric to local effect with such small numbers, and accounting for further links in a causative chain, remain beyond current modeling capabilities.” EPA, *Light Duty Vehicle Greenhouse Gas Standards and Corporate Average Fuel Economy*

Standards, Response to Comment Document for Joint Rulemaking at 4–102 (Docket EPA–OAR–HQ–2009–4782). EPA reached this conclusion after evaluating issues relating to potential improvements relevant to both temperature and oceanographic pH outputs. EPA’s ultimate finding was that “any potential for a specific impact on listed species in their habitats associated with these very small changes in average global temperature and ocean pH is too remote to trigger the threshold for ESA section 7(a)(2).” *Id.* EPA and NHTSA believe that the same conclusion will apply to the present final rule, given that the projected CO₂ emission reductions are comparable to or less than those projected for either of the light duty vehicle rules. See Section VII.D.2 and Table VII–41 of this Preamble; See also, e.g., *Ground Zero Center for Non-Violent Action v. U.S. Dept. of Navy*, 383 F. 3d 1082, 1091–92 (9th Cir. 2004) (where the likelihood of jeopardy to a species from a federal action is extremely remote, ESA does not require consultation).

M. Congressional Review Act (CRA)

This action is subject to the CRA, and the agencies will submit a rule report to each House of the Congress and to the Comptroller General of the United States. This action is a “major rule” as defined by 5 U.S.C. 804(2).

XV. EPA and NHTSA Statutory Authorities

As described below, the regulations being adopted are authorized separately for EPA and NHTSA under the agencies’ respective statutory authorities. See Section I for a discussion of these authorities.

A. EPA

Statutory authority for the vehicle controls is found in CAA section 202(a) (which authorizes standards for emissions of pollutants from new motor vehicles that emissions cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare), and CAA sections 202(d), 203–209, 216, and 301 (42 U.S.C. 7521(a), 7521(d), 7522–7543, 7550, and 7601).

EPA makes certain proposed rules available to the Science Advisory Board (SAB), including rules subject to 42 U.S.C. 4365 and rules which are not, but which EPA believes should be made available to the SAB. EPA provided information to the SAB about this rulemaking and on June 11, 2014, the chartered SAB discussed the recommendations of its work group on the planned action and agreed that no

further SAB consideration of the rule or its supporting science was merited. We note further that the substantial NAS report to NHTSA and to Congress evaluating medium- and heavy-duty truck fuel efficiency improvement opportunities (see Section I.A.2 (g) above) would serve as a surrogate for SAB consultation. See *American Petroleum Inst. v. EPA*, 665 F. 2d 1176, 1189 (D.C. Cir. 1981).

B. NHTSA

Statutory authority for the fuel consumption standards is found in section 103 of the Energy Independence and Security Act of 2007, 49 U.S.C. 32902(k). EISA authorizes a fuel efficiency improvement program, designed to achieve the maximum feasible improvement to be created for commercial medium- and heavy-duty on-highway vehicles and work trucks, to implement appropriate test methods, measurement metrics, fuel economy standards, and compliance and enforcement protocols that are appropriate, cost-effective and technologically feasible. To the extent motor vehicle safety is implicated, NHTSA’s authority to regulate it is also derived from the National Traffic and Motor Vehicle Safety Act, 49 U.S.C. 30101 *et seq.*

List of Subjects

40 CFR Part 9

Reporting and recordkeeping requirements.

40 CFR Part 22

Administrative practice and procedure, Air pollution control, Hazardous substances, Hazardous waste, Penalties, Pesticides and pests, Poison prevention, Water pollution control.

40 CFR Part 85

Confidential business information, Imports, Labeling, Motor vehicle pollution, Reporting and recordkeeping requirements, Research, Warranties.

40 CFR Part 86

Administrative practice and procedure, Confidential business information, Incorporation by reference, Labeling, Motor vehicle pollution, Reporting and recordkeeping requirements.

40 CFR Part 600

Administrative practice and procedure, Electric power, Fuel economy, Incorporation by reference, Labeling, Reporting and recordkeeping requirements.

¹⁰¹⁸ See, e.g., 73 FR 28212, 28300 (May 15, 2008); 73 FR 76249 (Dec. 16, 2008); Memorandum from David Longly Bernhardt, Solicitor, U.S. Department of the Interior re: “Guidance on the Applicability of the Endangered Species Act’s Consultation Requirements to Proposed Actions Involving the Emission of Greenhouse Gases” (Oct. 3, 2008).

40 CFR Part 1033

Administrative practice and procedure, Air pollution control.

40 CFR Parts 1036 and 1037

Environmental protection, Administrative practice and procedure, Air pollution control, Confidential business information, Incorporation by reference, Labeling, Motor vehicle pollution, Reporting and recordkeeping requirements, Warranties.

40 CFR Part 1039

Environmental protection, Administrative practice and procedure, Air pollution control, Confidential business information, Imports, Labeling, Penalties, Reporting and recordkeeping requirements, Warranties.

40 CFR Part 1042

Environmental protection, Administrative practice and procedure, Air pollution control, Confidential business information, Imports, Incorporation by reference, Labeling, Penalties, Reporting and recordkeeping requirements, Vessels, Warranties.

40 CFR Part 1043

Environmental protection, Administrative practice and procedure, Air pollution control, Imports, Incorporation by reference, Vessels,

Reporting and recordkeeping requirements.

40 CFR Parts 1065 and 1066

Administrative practice and procedure, Air pollution control, Incorporation by reference, Reporting and recordkeeping requirements, Research.

40 CFR Part 1068

Administrative practice and procedure, Confidential business information, Imports, Incorporation by reference, Motor vehicle pollution, Penalties, Reporting and recordkeeping requirements, Warranties.

49 CFR Parts 523, 534, and 535

Fuel economy, Reporting and recordkeeping requirements.

49 CFR Part 538

Administrative practice and procedure, Fuel economy, Motor vehicles, Reporting and recordkeeping requirements.

For the reasons set out in the Preamble, title 40, chapter I of the Code of Federal Regulations is amended as set forth below.

PART 9—OMB APPROVALS UNDER THE PAPERWORK REDUCTION ACT

■ 1. The authority citation for part 9 continues to read as follows:

Authority: 7 U.S.C. 135 *et seq.*, 136–136y; 15 U.S.C. 2001, 2003, 2005, 2006, 2601–2671; 21 U.S.C. 331j, 346a, 31 U.S.C. 9701; 33 U.S.C. 1251 *et seq.*, 1311, 1313d, 1314, 1318, 1321, 1326, 1330, 1342, 1344, 1345(d) and (e), 1361; E.O. 11735, 38 FR 21243, 3 CFR, 1971–1975 Comp. p. 973; 42 U.S.C. 241, 242b, 243, 246, 300f, 300g, 300g–1, 300g–2, 300g–3, 300g–4, 300g–5, 300g–6, 300j–1, 300j–2, 300j–3, 300j–4, 300j–9, 1857 *et seq.*, 6901–6992k, 7401–7671q, 7542, 9601–9657, 11023, 11048.

■ 2. In § 9.1 the table is amended by:

■ a. Adding in numerical order by CFR designation a new undesignated center heading “Control of Emissions from New and In-Use Heavy-Duty Highway Engines” and its entry in numerical order for “1036.825”;

■ b. Adding in numerical order by CFR designation a new undesignated center heading “Control of Emissions from New Heavy-Duty Motor Vehicles” and its entry in numerical order for “1037.825”; and

■ c. Adding in numerical order by CFR designation a new undesignated center heading “Control of NO_x, SO_x, and PM Emissions from Marine Engines and Vessels Subject to the MARPOL Protocol” and its entries in numerical order for “1043.40–1043.95”.

The additions read as follows:

§ 9.1 OMB approvals under the Paperwork Reduction Act.

* * * * *

40 CFR citation					OMB control No.
* * * * *					
Control of Emissions From New and In-Use Heavy-Duty Highway Engines					
1036.825					2060–0678
Control of Emissions From New Heavy-Duty Motor Vehicles					
1037.825					2060–0678
* * * * *					
Control of NO_x, SO_x, and PM Emissions From Marine Engines and Vessels Subject to the Marpol Protocol					
1043.40–1043.95					2060–0641
* * * * *					

* * * * *

PART 22—CONSOLIDATED RULES OF PRACTICE GOVERNING THE ADMINISTRATIVE ASSESSMENT OF CIVIL PENALTIES AND THE REVOCATION/TERMINATION OR SUSPENSION OF PERMITS

■ 3. The authority citation for part 22 continues to read as follows:

Authority: 7 U.S.C. 136(l); 15 U.S.C. 2615; 33 U.S.C. 1319, 1342, 1361, 1415 and 1418; 42 U.S.C. 300g–3(g), 6912, 6925, 6928, 6991e and 6992d; 42 U.S.C. 7413(d), 7524(c), 7545(d), 7547, 7601 and 7607(a), 9609, and 11045.

Subpart A—General

■ 4. Section 22.1 is amended by revising paragraph (a)(2) to read as follows:

§ 22.1 Scope of this part.

(a) * * *

(2) The assessment of any administrative civil penalty under sections 113(d), 205(c), 211(d) and 213(d) of the Clean Air Act, as amended (42 U.S.C. 7413(d), 7524(c), 7545(d) and 7547(d)), and a determination of nonconforming engines, vehicles or equipment under sections 207(c) and

213(d) of the Clean Air Act, as amended (42 U.S.C. 7541(c) and 7547(d));

* * * * *

Subpart C—Prehearing Procedures

■ 5. Section 22.34 is revised to read as follows:

§ 22.34 Supplemental rules governing the administrative assessment of civil penalties under the Clean Air Act.

(a) *Scope.* This section shall apply, in conjunction with §§ 22.1 through 22.32, in administrative proceedings to assess a civil penalty conducted under sections 113(d), 205(c), 211(d), and 213(d) of the Clean Air Act, as amended (42 U.S.C. 7413(d), 7524(c), 7545(d), and 7547(d)), and a determination of nonconforming engines, vehicles or equipment under sections 207(c) and 213(d) of the Clean Air Act, as amended (42 U.S.C. 7541(c) and 7547(d)). Where inconsistencies exist between this section and §§ 22.1 through 22.32, this section shall apply.

(b) *Issuance of notice.* Prior to the issuance of a final order assessing a civil penalty or a final determination of nonconforming engines, vehicles or equipment, the person to whom the order or determination is to be issued shall be given written notice of the proposed issuance of the order or determination. Service of a complaint or a consent agreement and final order pursuant to § 22.13 satisfies these notice requirements.

PART 85—CONTROL OF AIR POLLUTION FROM MOBILE SOURCES

■ 6. The authority citation for part 85 continues to read as follows:

Authority: 42 U.S.C. 7401–7671q.

Subpart F—Exemption of Clean Alternative Fuel Conversions from Tampering Prohibition

■ 7. Section 85.525 is revised to read as follows:

§ 85.525 Applicable standards.

To qualify for an exemption from the tampering prohibition, vehicles/engines that have been converted to operate on a different fuel must meet emission standards and related requirements as described in this section. The modified vehicle/engine must meet the requirements that applied for the OEM vehicle/engine, or the most stringent OEM vehicle/engine standards in any allowable grouping. Fleet average standards do not apply unless clean alternative fuel conversions are specifically listed as subject to the standards.

(a) If the vehicle/engine was certified with a Family Emission Limit for NO_x, NO_x+HC, NO_x+NMOG, or particulate matter, as noted on the vehicle/engine emission control information label, the modified vehicle/engine may not exceed this Family Emission Limit.

(b) Compliance with greenhouse gas emission standards is demonstrated as follows:

(1) Subject to the following exceptions and special provisions, compliance with light-duty vehicle greenhouse gas emission standards is demonstrated by complying with the N₂O and CH₄ standards and provisions set forth in 40 CFR 86.1818–12(f)(1) and the in-use CO₂ exhaust emission standard set forth in 40 CFR 86.1818–12(d) as determined by the OEM for the subconfiguration that is identical to the fuel conversion emission data vehicle (EDV):

(i) If the OEM complied with the light-duty greenhouse gas standards using the fleet averaging option for N₂O and CH₄, as allowed under 40 CFR 86.1818–12(f)(2), the calculations of the carbon-related exhaust emissions require the input of grams/mile values for N₂O and CH₄, and you are not required to demonstrate compliance with the standalone CH₄ and N₂O standards.

(ii) If the OEM complied with alternate standards for N₂O and/or CH₄, as allowed under 40 CFR 86.1818–12(f)(3), you may demonstrate compliance with the same alternate standards.

(iii) If the OEM complied with the nitrous oxide (N₂O) and methane (CH₄) standards and provisions set forth in 40 CFR 86.1818–12(f)(1) or (3), and the fuel conversion CO₂ measured value is lower than the in-use CO₂ exhaust emission standard, you also have the option to convert the difference between the in-use CO₂ exhaust emission standard and the fuel conversion CO₂ measured value into GHG equivalents of CH₄ and/or N₂O, using 298 g CO₂ to represent 1 g N₂O and 25 g CO₂ to represent 1 g CH₄. You may then subtract the applicable converted values from the fuel conversion measured values of CH₄ and/or N₂O to demonstrate compliance with the CH₄ and/or N₂O standards.

(iv) Optionally, compliance with greenhouse gas emission requirements may be demonstrated by comparing emissions from the vehicle prior to the fuel conversion to the emissions after the fuel conversion. This comparison must be based on FTP test results from the emission data vehicle (EDV) representing the pre-conversion test group. The sum of CO₂, CH₄, and N₂O shall be calculated for pre- and post-conversion FTP test results, where CH₄
